1 Introduction

The question of whether (and why) the digits of well-known constants of mathematics are statistically random in some sense has long fascinated mathematicians. Indeed, one prime motivation in computing and analyzing digits of $\pi$ is to explore the age-old question of whether and why these digits appear “random.” The first computation on ENIAC in 1949 of $\pi$ to 2037 decimal places was proposed by John von Neumann so as to shed some light on the distribution of $\pi$ (and of $e$) [8, pp. 277–281].

Since then, numerous computer-based statistical checks of the digits of $\pi$, for instance, so far have failed to disclose any deviation from reasonable statistical norms. See, for instance, Table 1, which presents the counts of individual hexadecimal digits among the first trillion hex digits, as obtained by Yasumasa Kanada. By contrast,

the early computations did reveal provable abnormalities in the behavior of $e$ [10, §11.2]. Figure 2 shows $\pi$ as a random walk drawn as we describe below.

In the first part of this paper we look at various classical numbers—such as $\sqrt{2}$ and $\pi$—and discuss current knowledge regarding normality of such irrational numbers. In the second part of the paper we analyze roughly four trillion hexadecimal digits of $\pi$. This is only possible because of several extraordinary recent computations [22]. We describe a notion of normality for finite strings and then conclude that the four trillion hexadecimal digits examined are normal in that sense. We then propose a Poisson process model of normality of the digits of a number and deduce that in this model, it is extraordinarily likely that $\pi$ is asymptotically normal base 16, given the behavior of its initial segment.
1.1 Normality of real numbers

In each of the pictures in Figures 2 through 5, a digit string for a given number is used to determine the angle of unit steps (multiples of 120 degrees base 3, 90 degrees base four, etc), while the color is shifted up the spectrum after a fixed number of steps (red-orange-yellow-green-cyan-blue-purple-red). In Figure 2 we show a walk on the first billion base 4 digits of $\pi$. This may be viewed in more detail on line at http://gigapan.org/gigapans/e76a680ea683a233677109fddd36304a. In Figures 3 through 5, we similarly illustrate Theorems 2 through 8 below. We note that the behavior or random walks of various numbers constructed to be provably normal looks entirely different from the expected behavior of a genuine pseudo random walk as in Figure 1.

![Figure 1: A uniform pseudo-random walk.](image)

In the following, given some positive integer base $b$, we will say that a real number $\alpha$ is $b$-normal if every $m$-long string of base-$b$ digits appears in the base-$b$ expansion of $\alpha$ with precisely the expected limiting frequency $1/b^m$. It follows, from basic measure theory, that almost all real numbers are $b$-normal for any specific base $b$ and even for all bases simultaneously. But proving normality for specific constants of interest in mathematics has proven remarkably difficult.
Borel was the first to conjecture that all irrational algebraic numbers are \( b \)-normal for every integer \( b \geq 2 \). Yet not a single instance of this conjecture has ever been proven. We do not even know for certain whether or not the limiting frequency of zeroes in the binary expansion of \( \sqrt{2} \) is one-half, although numerous large statistical analyses have failed to show any significant deviation from statistical normals.

The only substantive result along this line, as far as the present authors are aware, is the following: *If a real \( y \) has algebraic degree \( D > 1 \), then the number \( \#(|y|, N) \) of 1-bits in the binary expansion of \(|y|\) through bit position \( N \) satisfies*

\[
\#(|y|, N) > CN^{1/D}
\]

for a positive number \( C \) (depending on \( y \)) and all sufficiently large \( N \) [2]. For example, there must be at least \( \sqrt{N} \) 1-bits in the first \( N \) bits in the binary expansion of \( \sqrt{2} \), in the limit. But this is clearly weaker than desired, since the limiting ratio is almost certainly \( 1/2 \).

The same can be said for \( \pi \) and other basic constants, such as \( e, \log 2 \) and \( \zeta(3) \). Clearly any result (one way or the other) for one of these constants would be a mathematical development of the first magnitude.

We do record the following known stability result [9, pp. 165–166]:

\[
\text{Figure 2: A random walk on the first two billion bits of } \pi \text{ (normal?).}
\]
Theorem 1 If $\alpha$ is normal in base $b$ and $r, s$ are positive rational numbers then $r\alpha + s$ is also normal in base $b$.

1.2 The Champernowne number and relatives

The first mathematical constant proven to be 10-normal is the Champernowne number, which is defined as the concatenation of the decimal values of the positive integers, i.e., $C_{10} = 0.12345678910111213141516\ldots$, which can also be written as

$$C_{10} = \sum_{n=1}^{\infty} \sum_{k=10^{n-1}}^{10^n-1} \frac{k}{10^{kn-9}\sum_{k=1}^{n-1} 10^k(n-k)}.$$ 

Champernowne proved that $C_{10}$ is 10-normal in 1933 [14]. This was later extended to base-$b$ normality (for base-$b$ versions of the Champernowne constant).

In 1946, Copeland and Erdős established that the corresponding concatenation of primes $0.23571113171923\ldots$ and also the concatenation of composites $0.46891012141516\ldots$, among others, are also 10-normal [15]. In general they proved:

Theorem 2 ([15]) If $a_1, a_2, \cdots$ is an increasing sequence of integers such that for every $\theta < 1$ the number of $a_i$’s up to $N$ exceeds $N^\theta$ provided $N$ is sufficiently large, then the infinite decimal

$$0.a_1a_2a_3\ldots$$

is normal with respect to the base $\beta$ in which these integers are expressed.

This clearly applies the Champernowne numbers (Figure 5(d)) and to the primes of the form $ak + c$ with $a$ and $c$ relatively prime in any given base (Figure 5(c)) and to the integers which are the sum of two squares (since every prime of the form $4k + 1$ is included). In further illustration, using the primes in binary lead to normality in base two of the number

$$0.10111011110110110001100110111101101111011010101011011111\ldots,$$

as shown as a random walk in Figure 3.

Some related results were established by Schmidt, including the following [20]. Write $p \sim q$ if there are positive integers $r$ and $s$ such that $p^r = q^s$. Then

Theorem 3 If $p \sim q$, then any real number that is $p$-normal is also $q$-normal. However, if $p \not\sim q$, then there are uncountably many $p$-normal reals that are not $q$-normal.
Queffelec [19] described the above result in a recent survey which also presented the following theorem:

**Theorem 4 (Korobov)** Numbers of the form $\sum_{k} p^{2k} \cdot q^{2k}$, where $p > 1$ and $q > 1$ are relatively prime, are $q$-normal.

We will return to such numbers in Theorem 5 of Section 4. Nonetheless, we are still completely in the dark as to the $b$-normality of “natural” constants of mathematics.

## 2 The BBP formula for $\pi$

In 1996, one of the present authors (Bailey), together with Peter Borwein (brother of Jonathan Borwein) and Simon Plouffe, published what is now known as the BBP formula for $\pi$ [3], [9, Ch. 3]:

$$\pi = \sum_{k=0}^{\infty} \frac{1}{16^k} \left( \frac{4}{8k+1} - \frac{2}{8k+4} - \frac{1}{8k+5} - \frac{1}{8k+6} \right).$$  \hspace{1cm} (3)$$

This formula has the remarkable property that it permits one to directly calculate binary or hexadecimal digits of $\pi$ beginning at an arbitrary starting position, without needing to calculate any of the preceding digits. The resulting simple algorithm requires only minimal memory, does not require multiple-precision arithmetic, and
is very well suited to highly parallel computation. The cost of this scheme increases only slightly faster than the index of the starting position.

The BBP formula (3) was discovered via a computer-based search using the PSLQ integer relation detection algorithm of mathematician-sculptor Helaman Ferguson [4], in a process that some have described as an exercise in “reverse mathematical engineering.” The motivation for this search was the earlier observation by the authors of [3] that log 2 also has this arbitrary position digit calculating property. This can be seen by analyzing the classical formula

$$\log 2 = \sum_{k=1}^{\infty} \frac{1}{k2^k}, \quad (4)$$

which has been known at least since the time of Euler, and which is closely related to the functional equation for the dilogarithm.

The digit-calculating scheme can be demonstrated for the log 2 formula (4) as follows. Let \( r \mod 1 \) denote the fractional part of a nonnegative real number \( r \), and let \( d \) be a nonnegative integer. Then the binary fraction of log 2 after the “decimal” point has been shifted to the right \( d \) places can be written as

$$\begin{align*}
(2^d \log 2) \mod 1 &= \left( \sum_{k=1}^{d} \frac{2^{d-k}}{k} \mod 1 + \sum_{k=d+1}^{\infty} \frac{2^{d-k}}{k} \mod 1 \right) \mod 1 \\
&= \left( \sum_{k=1}^{d} \frac{2^{d-k} \mod k}{k} \mod 1 + \sum_{k=d+1}^{\infty} \frac{2^{d-k} \mod k}{k} \mod 1 \right) \mod 1,
\end{align*} \quad (5)$$

where “mod \( k \)” has been inserted in the numerator of first term since we are only interested in the fractional part of the result after division. The operation \( 2^{d-k} \mod k \) can be performed very rapidly by means of the binary algorithm for exponentiation, where all of the intermediate multiplication results are reduced modulo \( k \) at each step. This algorithm, together with the division and summation operations indicated in the first term, can be performed in ordinary double-precision floating-point arithmetic, or, for very large calculations, by using quad- or oct-precision arithmetic. Expressing the final fractional value in binary notation yields a string of digits corresponding to the binary digits of log 2 beginning immediately after the first \( d \) digits. Applying this same scheme to the four terms of (3) yields binary digits of \( \pi \) at an arbitrary starting position.

3 BBP formulas and normality

Interest in BBP-type formulas was heightened by the 2001 observation, by one of the present authors (Bailey) and Richard Crandall, that the normality of BBP-type constants such as π, π², log 2 and Catalan’s constant can be reduced to a certain hypothesis regarding the behavior of a class of chaotic iterations [5], [9, pg. 141–173]. No proof is known for this general hypothesis, but even proofs in specific instances would be quite interesting. For example, if it could be established that the iteration given by \( w_0 = 0 \), and

\[
    w_n = \left( 2w_{n-1} + \frac{1}{n} \right) \mod 1
\]

is equi-distributed in \([0, 1)\) (i.e., is a “good” pseudo-random number generator), then, according to the Bailey-Crandall result, it would follow that log 2 is 2-normal. In a similar vein, if it could be established that the iteration given by \( x_0 = 0 \) and

\[
    x_n = \left( 16x_{n-1} + \frac{120n^2 - 89n + 16}{512n^4 - 1024n^3 + 712n^2 - 206n + 21} \right) \mod 1
\]

is equi-distributed in \([0, 1)\), then it would follow that \( \pi \) is 2-normal.

3.1 The Erdős-Borwein constants

In a base \( b \geq 2 \), we define the Erdős-(Peter) Borwein constant \( EB(b) \) by the Lambert series [10]:

\[
    EB(b) := \sum_{n \geq 1} \frac{1}{b^n - 1} = \sum_{n \geq 1} \frac{\sigma(n)}{b^n},
\]

where \( \sigma_k \) the sum of the k-th power of the divisors and \( \sigma = \sigma_1 \). It is known that the numbers \( \sum 1/(q^n - r) \) are irrational for \( r \) rational and \( q = 1/b, b = 2, 3, ... \) [11]. Whence, it is interesting to consider their normality.

Crandall has used the BBP-like structure made obvious in (8), and some non-trivial knowledge of the arithmetic properties of \( \sigma \) to establish results such as that the googol-th bit–i.e., the bit in position \( 10^{100} \) to the right of the floating point—is a 1.

Crandall also computed the full first \( 2^{43} \) bits of \( EB(2) \) (a Terabyte in about a day), and finds that there are 4359105565638 zeroes and 4436987456570 ones. There is corresponding variation in the second and third place in the single digit hex
distributions. This certainly leaves some doubt as to its normality. See also Figure 5(e).

Our own more modest computations of $EB(10)$ base-ten again leave it far from clear that $EB(10)$ is 10-normal. For instance, Crandall finds that in the first 10000 decimal positions after the quintillionth digit $10^{18}$, the respective digit counts for digits 0, 1, 2, 3, 4, 5, 6, 7, 8, 9 are 104, 82, 87, 100, 73, 126, 87, 123, 114, 104. See also Figure 5(f).

The identity

$$\sum_{n \geq 1} \frac{q^n}{1 - q^n} = \sum_{n \geq 1} q^{n^2} \frac{1 + q^n}{1 - q^n},$$

for $|q| < 1$, due to Clausen, is what we used for computational purposes, as did Crandall [16].

4 A class of provably normal constants

In 2002, Bailey and Crandall showed that given a real number $r$ in $[0, 1)$, with $r_k$ denoting the $k$-th binary digit of $r$, the real number

$$\alpha_{2,3}(r) = \sum_{k=0}^{\infty} \frac{1}{3^k 2^{3^k + r_k}}$$

is 2-normal. It can be seen that if $r \neq s$, then $\alpha_{2,3}(r) \neq \alpha_{2,3}(s)$, so that these constants are all distinct. Since $r$ can range over the unit interval, this class of constants is uncountably infinite. A similar result applies if 2 and 3 in this formula are replaced by any pair of coprime integers $(b, c)$ with $b \geq 2$ and $c \geq 2$ [6], [9, pg. 141–173]. So, for example, the constant $\alpha_{2,3}(0) = \sum_{k \geq 0} 1/(3^k 2^{3^k}) = 0.5418836808315030\ldots$ is provably 2-normal. This special case was proven by Stoneham in 1973 [18].

More recently, one of the present authors (Bailey) and Michal Misiewicz were able to establish this normality result by a simpler argument, by utilizing techniques of ergodic theory [7] and a “hot spot” lemma. In the Appendix, we present proofs of the following two results, illustrating the usage of the “hot spot” lemma:

**Theorem 5** The constant

$$\alpha_{2,3}(0) = \sum_{k=0}^{\infty} \frac{1}{3^k 2^{3^k}}$$

is 2-normal.
Theorem 6  Given coprime integers $b \geq 2$ and $c \geq 2$, the constant
\[
\alpha_{b,c}(0) = \sum_{k=0}^{\infty} \frac{1}{c^k b^k}
\]
is $b$-normal.

The first proof is adapted from [7], but the second proof has not previously been published.

5  A non-normality result

Almost as interesting is the following fact:

Theorem 7 (Non-normality) $\alpha_{2,3}(0)$ is not 6-normal.

Discussion: In the following, we will use $\alpha$ to mean $\alpha_{2,3}(0)$. Note that the base-6 digits immediately following position $n$ in the base-6 expansion of $\alpha$ can be obtained by computing $6^n \alpha \mod 1$, which can be written as follows:

\[
(6^n \alpha) \mod 1 = \left( \sum_{m=0}^{\lfloor \log_3 n \rfloor} 3^{n-m} 2^{n-3m} \right) \mod 1 + \left( \sum_{m=\lfloor \log_3 n \rfloor+1}^{\infty} 3^{n-m} 2^{n-3m} \right) \mod 1.
\]

Now note that the first portion of this expression is zero, since all terms of the summation are integers. That leaves the second expression.

Consider first the special case when $n = 3^m$, where $m \geq 1$ is an integer. The first three terms of the second summation are:

\[
\begin{align*}
3^{3^m-(m+1)} 2^{3^m-3^{m+1}} &= 3^{3^m-m-12} 2^{3^m-3^{m+1}} = (3/4)^{3^m}/3^{m+1}, \\
3^{3^m-(m+2)} 2^{3^m-3^{m+2}} &= 3^{3^m-m-28} 2^{3^m-3^{m+2}} = (3/8)^{3^m}/3^{m+2}, \\
3^{3^m-(m+3)} 2^{3^m-3^{m+3}} &= 3^{3^m-m-32} 2^{3^m-3^{m+3}} = (3/26)^{3^m}/3^{m+3}.
\end{align*}
\]

Note that for $m \geq 3$, we can generously bound the sum of all these terms by $1 + 10^{-6}$ times the first term, and by ratios arbitrarily closer to one for larger $m$. Thus we have $(6^{3^m} \alpha) \mod 1 \approx (3/4)^{3^m}/3^{m+1}$, and this approximation is as accurate as desired (in ratio) for all sufficiently large $m$. 

10

</table>

Given the very small size of the expression $(3/4)^{3^m}/3^{m+1}$ for even moderate-sized $m$, it is clear the base-6 expansion will have very long stretches of zeroes beginning at positions $3^m + 1$. For example, by explicitly computing $\alpha$ to high precision, one can obtain the counts shown in Table 2 of consecutive zeroes $Z_m$ that immediately follow position $3^m$ in the base-6 expansion of $\alpha$.

Examining Table 2, there 14256 zeroes in these ten segments, which, including the last segment, span the first $59049 + 9487 = 68536$ base-6 digits of $\alpha$. In this tabulation we have of course ignored the many zeroes in the large “random” segments of the expansion. Thus the fraction of the first 68536 digits that are zero is at least $\frac{14256}{68536} = 0.2080074\ldots$. A more careful analysis shows that the limiting ratio

$$\lim_{m \to \infty} \frac{\sum_{m \geq 1} Z_m}{3^m + Z_m} = \frac{3 \cdot \log_6(4/3)}{2 \cdot \frac{\log_6(4/3)}{1 + \log_6(4/3)}} = \frac{1}{2} \log_2(4/3) = 0.2075187496\ldots,$$

which is significantly more than the expected value $1/6 = 0.16666\ldots$, thus establishing the non-normality base 6 of $\alpha$. A completely detailed proof is presented in the Appendix. The Appendix also gives a full proof of this generalization of Theorem 7:

**Theorem 8 (Non-normality)** Given coprime integers $b \geq 2$ and $c \geq 2$, the constant

$$\alpha_{b,c}(0) : = \sum_{k \geq 1} \frac{1}{e^{b^k} e^k}$$

(14)
is $b$-normal but is not $bc$-normal.

We further conjecture that this result is true not just for the class $\alpha_{b,c}(0)$, but also for all $\alpha_{b,c}(r)$ where $r$ is the argument in (9) above.

The proofs of Theorems 7 and 8 given in the Appendix are adapted from [1].

In Figure 4 the non-normality of $\alpha_{2,3}$ base 6 is very visible.

Figure 4: A random walk on the first 50,000 bits of $\alpha_{2,3}(0)$ base six (abnormal).

We now turn to an analysis of the normality of finite strings.

6 Normality for words

Let $x$ be a (finite) binary word. We denote by $N^m_i(x)$ the number of occurrences of the $i$th word of length $m$ ($1 \leq i \leq 2^m$), ordered lexicographically, where $|x|_m = \lceil |x|/m \rceil$ is the number of (contiguous, non-overlapping) of length $m$ words in $x$. The prefix of length $n$ of the infinite (binary) sequence $x = x_1x_2\ldots x_m\ldots$ is denoted by $x \upharpoonright n = x_1x_2\ldots x_n$.

**Definition 1** ([12, 13]) Let $\varepsilon > 0$ and $m$ be a positive integer. We say:

1. $x$ is $(\varepsilon,m)$-normal if, for every $1 \leq i \leq 2^m$,
   
   $\left| \frac{N^m_i(x)}{|x|_m} - \frac{1}{2^m} \right| \leq \varepsilon$.

2. $x$ is $m$-normal if, for every $1 \leq i \leq 2^m$,

   $\left| \frac{N^m_i(x)}{|x|_m} - \frac{1}{2^m} \right| \leq \sqrt{\log_2 |x|/|x|}. \quad (15)$

3. $x$ is normal if it is $m$-normal for every $1 \leq m \leq \log_2 (\log_2 |x|)$.

If for every positive integer $n$, the word $x \upharpoonright n$ is normal, then $x$ is normal, but the converse is not necessarily true (because $x$ can be normal but with a different “speed”).

12
Figure 5: Random walks on prefixes of various numbers.
7 Testing normality of prefixes of $\pi$

We had access to an extraordinary data-set, thanks to recent record computations by Kondo and Yee, of $\pi$ initially to five trillion hexadecimal (base 16) places in August 2010 and then to ten trillion in October 2011 [22]. We first converted these bits—which Kondo and Yee had confirmed by a computation with (3)—to a true binary string of bits using the Python module binascii.

All input lines contained an even number of characters so it was easy to convert pairs of hexadecimal digits to bytes.

```python
import sys, binascii
for line in sys.stdin.readlines():
    sys.stdout.write(binascii.unhexlify(line.strip()))
```

For our normality test we needed to split a big binary string of length $n$ into $\lfloor n/k \rfloor$ pieces (non-overlapping words) of length $k = 1, 2, \ldots, \log \log n$. We use the term word to denote a binary string of length $k$. We then proceeded to calculate the minimum and maximum occurrences of such words.

This calculation is done by running the following Algorithm 1 once for each different value of $k$.

---

**Algorithm 1:** Frequency range of words of a given length.

**Input:** Binary string $X$, word length $k$

**Output:** Minimum and maximum counts over all possible $2^k$ words of length $k$ in string $X$

integer array $counts[0, \ldots, 2^k - 1] = [0, 0, \ldots, 0]$;

for $i = 0$ to $|X| - k$ step $k$ do

    $w = \text{integer}(X[i, \ldots, i + k - 1])$;
    increment $counts[w]$;

return min($counts$), max($counts$);

---

It is essential to do an efficient streaming implementation of Algorithm 1 so that the actual bits of input $X$ are only read into main memory as needed.

Finally to check that these minimum and maximum frequencies satisfy the expected range for the normality test we used the following Python code snippet to generate a table using our earlier formula (15):
import math, sys
n=int(sys.argv[1]) # n = |X|
r = int(math.floor(math.log(math.log(n,2),2))) # r = lg lg n
m1,m2=[0]*(r+1),[0]*(r+1)
sqrtV = math.sqrt(math.log(n,2)/n)
for k in range(1,r+1):
    floorNk = math.floor(n/k)
    m1[k] = int(math.floor(((1.0/2.0**i)-sqrtV)*floorNk))
    m2[k] = int(math.ceil((sqrtV+(1.0/2.0**k))*floorNk))

We tested normality for the prefix of $N = 15,925,868,541,400$ bits of $\pi$—nearly 16 trillion bits—and we have found it to be within the normality range as described above. passed our expectedCheck.py test script.

8 Normality of $\pi$

We have tested the prefix of $N = 15,925,868,541,400$ bits of $\pi$—nearly 16 trillion bits—and we have found it to be normal as described above.

Does this “information” tell us anything about the classical normality of $\pi$? In the next subsection, we will use a Poisson process model to provide an affirmative answer to this question.

8.1 A Poisson process model

We denote by

$$b = b(1) b(2) \ldots b(n) \ldots$$

</table>
the (infinite) binary expansion of $\pi$ ($b$ is a computable function) and by

$$b \upharpoonright n = b(1)b(2)\ldots b(n)$$

the finite prefix of $b$ of length $n$.

We base our model on the distribution on 1's and 0's only, i.e., we work with $N^1_0 (b \upharpoonright n)$, the number of occurrences of 1's in $b \upharpoonright n$, so $N^1_0 (b \upharpoonright n) = n - N^1_1 (b \upharpoonright n)$. A similar, slightly more elaborate model, can be developed for words of any length.

The number $N^1_1 (b \upharpoonright n)$ can be connected with $\pi$ by means of a counting (Poisson) process [17]:

$$Y_n = \# \{ j \mid 1 \leq j \leq n, \ b(j) = 1 \}, \ n = 1, 2, \ldots$$

$$Y_0 = 0,$$

where $Y_n = N^1_1 (b \upharpoonright n)$, $n = 1, 2, \ldots$

**Theorem 9** If $\pi$ is normal, then $\{Y_n, n = 0, 1, 2, \ldots\}$ can be approximated by a homogenous Poisson process with intensity $\lambda = 0.5$.

**Proof.** By construction, $\{Y_n, n = 0, 1, 2, \ldots\}$ is a Poisson process with an unspecified parameter $\lambda$. Hence $Y_n$ is a random variable with parameter $n\lambda$ with the following properties: $E (Y_n) = V (Y_n) = n\lambda$, $\lim_{n \to \infty} Y_n = \infty$ almost sure.

We apply Chebysev’s inequality, so for every $c > 0$,

$$P \left( |Y_n - E (Y_n)| < c \right) \geq 1 - \frac{V (Y_n)}{c^2},$$

we have

$$P \left( |Y_n - n\lambda| < c \right) \geq 1 - \frac{n\lambda}{c^2},$$

hence

$$P \left( \left| \frac{Y_n}{n} - \lambda \right| < \frac{c}{n} \right) \geq 1 - \frac{n\lambda}{c^2}.$$
If $\pi$ is normal, then
\[
\left| N_1^1 (x_{(n)}) - \frac{1}{2} \right| \leq \varepsilon = \sqrt{\frac{\log_2 n}{n}}
\]
or
\[
\left| Y_n - \frac{1}{2} \right| \leq \varepsilon = \sqrt{\frac{\log_2 n}{n}}.
\] (17)

If we identify the random event in relation (16) and the certain event in relation (17) we get $\lambda = 1/2$ and
\[
P \left( \left| \frac{Y_n}{n} - \frac{1}{2} \right| < \sqrt{\frac{\log_2 n}{n}} \right) \geq 1 - \frac{1}{2 \log_2 n}.
\]

QED

A Poisson process with intensity $\lambda$ has the following properties [18]:

- The Poisson process $\{Y_n, n = 0, 1, 2, \ldots\}$ has independent increments.

- For $n > r$, $Y_n - Y_r$ has a Poisson distribution with parameter $\lambda(n-r)$, and $Y_n - Y_r$ is independent of $\{Y_t, t \leq r\}$.

Let us denote the positions where 1s occur (jump moments) by
\[
\tau_r = \inf \{n \mid Y_n = r\}, \ r = 1, 2, ...
\]

Then
\[
Y_n = 0, \ n < \tau_1,
\]
\[
Y_n = r, \ \tau_r \leq n < \tau_{r+1}.
\]

With the convention $\tau_0 = 0$, we can introduce the sojourn times, or inter-arrival times
\[
T_r = \tau_r - \tau_{r-1}, \ r = 1, 2, ...
\]

Note that the sojourn times represent the distances between two successive 1s. Thus, for the word $10^s1$ the sojourn time is $s + 1$.  

17
• \( \{T_r, r = 1, 2, \ldots\} \) is a sequence of independent, identical distributed random variables, with the Exponential distribution \( \text{Expo}(\lambda) \). Then

\[
E(T_r) = \frac{1}{\lambda}, \quad V(T_r) = \frac{1}{\lambda^2}.
\]

Note that the jump moments \( \tau_r = T_1 + \ldots + T_r \) have an Erlang distribution with parameters \((r; \lambda)\), hence

\[
E(T_r) = \frac{r}{\lambda}, \quad V(T_r) = \frac{r}{\lambda^2}.
\]

**Corollary 1** If \( \pi \) is normal, then the sojourn times \( \{T_r, r = 1, 2, \ldots\} \) form a sequence of independent, identical distributed random variables, with the Exponential distribution \( \text{Expo}(1/2) \). Hence

\[
P(T_r > t_r, r = 1, \ldots, k) = \prod_{r=1}^{k} \left( \exp\left( -\frac{t_r}{2} \right) \right) = \exp\left( -\frac{1}{2} \sum_{r=1}^{k} t_r \right).
\]

**8.2 Testing the hypothesis “\( \pi \) is normal”**

We test the hypothesis \( H: \text{“} \pi \text{ is normal} \) against the alternative \( H_A: \text{“} \pi \text{ is not normal} \). If \( H \) is true, then for every \( d \) there exists \( K_d \) such that the sojourn time exceeds the value \( d \) if we wait long enough, up to the rank \((K_d + 1)\):

\[
P(T_1 \leq d, \ldots, T_{K_d} \leq d, T_{K_d+1} > d \mid H \text{ true}) = \prod_{r=1}^{K_d} \left( 1 - \exp\left( -\frac{d}{2} \right) \right) \cdot \exp\left( -\frac{d}{2} \right)
\]

\[
= \exp\left( -\frac{d}{2} \right) \left( 1 - \exp\left( -\frac{d}{2} \right) \right)^{K_d} > 0.
\]

We can base our decision of accepting/rejecting normality (hypothesis \( H \)) on the following implication: “\( \pi \) is a normal sequence” implies “for every \( d \) there exists \( K_d \) such that \( P(T_1 \leq d, \ldots, T_{K_d} \leq d, T_{K_d+1} > d) > 0 \),

As one cannot explore the whole sequence \( \pi \), we deal with an evidence body represented by a prefix of \( \pi \), of length \( N \). In this evidence body, we look for the largest value \( d_{\text{max}} \) for which a rank \( K_{d_{\text{max}}} \) can be identified or, equivalently, we look for the first value \((d+1)\) which is not reached by the sojourn time \( T \). Accordingly, the decision of accepting/rejecting the hypothesis \( H: \text{“} \pi \text{ is normal} \) is taken according to the following algorithm:
• If there is no such $d_{\text{max}}$ in the evidence body, we conclude that the sequence $\pi$ is normal.

• If $d_{\text{max}}$ and the corresponding $K_{d_{\text{max}}}$ exist, we can decide that the sequence $\pi$ is not normal. The decision is based on the event

$$\{T_1 \leq d_{\text{max}}, \ldots, T_{K_{d_{\text{max}}}} \leq d_{\text{max}}, T_{K_{d_{\text{max}}}+1} > d_{\text{max}}\}$$

whose probability is

$$P(T_1 \leq d_{\text{max}}, \ldots, T_{K_{d_{\text{max}}}} \leq d_{\text{max}}, T_{K_{d_{\text{max}}}+1} > d_{\text{max}}) = \exp \left(-\frac{d_{\text{max}}}{2}\right) \left(1 - \exp \left(-\frac{d_{\text{max}}}{2}\right)\right)^{K_{d_{\text{max}}}}.$$

We interpret the above probability as the decision “$\pi$ is normal” has credibility equal to

$$1 - \exp \left(-\frac{d_{\text{max}}}{2}\right) \left(1 - \exp \left(-\frac{d_{\text{max}}}{2}\right)\right)^{K_{d_{\text{max}}}}.$$

### 8.3 Results

Suppose first that the evidence body is represented by a prefix of 400 million bits of $\pi$. The $d$–values and their corresponding ranks $K_d$ are given in Table 4; max $K_d$=100317701.

The value $d = 28$ has the property that for every $K$, the event

$$\{T_1 \leq 28, \ldots, T_K \leq 28, T_{K+1} > 28\}$$

has not been identified in the evidence body, so, based on the algorithm in Section 8.2, the decision “$\pi$ is not normal” has credibility

$$P(T_s \leq 27, \ s = 1, \ldots, 100317701, T_{100317702} > 27) = \left(1 - \exp \left(-\frac{27}{2}\right)\right)^{100317701} \cdot \exp \left(-\frac{27}{2}\right) = 2.5576 \times 10^{-66}.$$

Suppose now that the evidence body has increased to the prefix of $\pi$ of $N = 15925868541400$ bits. The $d$–values and their corresponding ranks $K_d$ are given in following Table 5; max $K_d$ = 9274770297096.

The value $d = 43$ has the property that for every $K$, the event

$$\{T_1 \leq 43, \ldots, T_K \leq 43, T_{K+1} > 43\}$$

has not been identified in the evidence body, so, based on the algorithm in Section 8.2, the decision “$\pi$ is not normal” has credibility

$$P (T_s \leq 42, s = 1, \ldots, 9274770297096, T_{9274770297097} > 42)$$

$$= \left(1 - \exp\left(-\frac{42}{2}\right)^{9274770297096}\right) \cdot \exp\left(-\frac{42}{2}\right) = 4.3497 \times 10^{-3064}.$$

9 Conclusion

A prime motivation in computing and analyzing digits of $\pi$ is to explore the age-old question of whether and why these digits appear “random.” Numerous computer-based statistical checks of the digits of $\pi$ have failed to disclose any deviation from reasonable statistical norms. A new avenue for studying the normality of $\pi$ was explored: we proved that the prefix of length 15, 925, 868, 541, 400 bits of $\pi$ is normal when viewed as a binary word [12].

This result was used in a Poisson process model to show that the probability that $\pi$ is not normal is extraordinarily small, reinforcing the empirical evidence we have presented evidence for the normality of $\pi$. In future work we intend to look methodically at other numerical constants.

10 Appendix

In the following, we will utilize the following result from [7]. Let $A(\alpha, y, n, m)$ denote the count of occurrences where the $m$-long binary string $y$ is found to start at position $p$ in the binary expansion of $\alpha$, where $1 \leq p \leq n$.

Lemma 1 (“Hot Spot” Lemma): If $x$ is not $b$-normal, then there is some $y \in [0, 1)$ with the property

$$\lim \inf_{m \to \infty} \lim \sup_{n \to \infty} \frac{b^m A(x, y, n, m)}{n} = \infty. \quad (18)$$

21
Conversely, if for all \( y \in [0,1) \),
\[
\liminf_{m \to \infty} \limsup_{n \to \infty} \frac{b^m A(x, y, n, m)}{n} < \infty,
\]
(19)
then \( x \) is \( b \)-normal.

Note that Lemma 1 implies that if a real constant \( \alpha \) is not \( b \)-normal, then there must exist some interval \([r_1, s_1]\) with the property that successive shifts of the base-\( b \) expansion of \( \alpha \) visit \([r_1, s_1]\) ten times more frequently, in the limit, relative to its length; there must be another interval \([r_2, s_2]\) that is visited 100 times more often relative to its length; there must be a third interval \([r_3, s_3]\) that is visited 1,000 times more often relative to its length; etc. Furthermore, there exists at least one real number \( y \) (a “hot spot”) such that sufficiently small neighborhoods of \( y \) are visited too often by an arbitrarily large factor, relative to the lengths of these neighborhoods. On the other hand, if it can be established that no subinterval of the unit interval is visited 1,000 times (for instance) more often in the limit relative to its length, then this suffices to prove that the constant in question is \( b \)-normal (and thus that each subinterval is visited with precisely the correct frequency, in the limit, relative to the size of the subinterval).

Here are two simple examples of the “hot spots” of non-normal decimal numbers. First, consider the fraction \( 1/28 \). Obviously this is not a 10-normal number since its decimal expansion repeats. It is easy to see by examining its decimal expansion that it possesses six base-10 hot spots, namely \( 1/7, 2/7, \ldots, 6/7 \). As a second example, consider \( \sum_{n \geq 1} 10^{-n^2} \), which is irrational but also clearly not 10-normal. This has zero as a base-10 hot spot.

We will first establish 2-normality for the constant \( \alpha_{2,3} \). This result was established first by Stoneham [18] and more recently in [6]. Here we reprise a simpler proof that was first presented in [7].

**Proof of Theorem 5:** \( \alpha_{2,3} = \sum_{m=0}^{\infty} 1/(3^m 2^{3m}) \) is 2-normal.

First we note that the successive shifted binary fractions of \( \alpha = \alpha_{2,3} \) can be written as
\[
2^n \alpha \mod 1 = \left( \sum_{m=0}^{\lfloor \log_3 n \rfloor} \frac{2^{n-3m} \mod 3^m}{3^m} \right) \mod 1 + \sum_{m=\lfloor \log_3 n \rfloor+1}^{\infty} \frac{2^{n-3m}}{3^m}.
\]
(20)
As it turns out, the first term of this expression can be generated by means of the recursion \( z_0 = 0 \) and, for \( n \geq 1 \), \( z_n = (2z_{n-1} + r_n) \mod 1 \), where \( r_n = 1/n \) if \( n = 3^k \).
for some integer $k$, and zero otherwise. The first few members of the $z$ sequence are given as follows:

$$
0, 0,
1, 2, 1, 2, 1, 2,
3, 3, 3, 3, 3, 3,
4, 8, 7, 5, 1, 2,
9, 9, 9, 9, 9, 9,
13, 26, 25, 23, 19, 11, 22, 17, 7, 14, 1, 2, 4, 8, 16, 5,
27, 27, 27, 27, 27, 27, 27, 27, 27, 27, 27, 27, 27, 27, 27,
10, 20, 27, 27,
$$

(repeated 3 times), etc. (21)

It can be shown, via straightforward combinatorial arguments [6], that indeed this sequence has the pattern evident here: It is a concatenation of triply repeated segments, where each individual segment consists of fractions with numerators, at stage $m$, that range over all integers relatively prime to the denominator $3^m$. From this pattern it follows that if $n < 3^{p+1}$, then $z_n$ is a multiple of $1/3^p$, and furthermore that the set $(z_k, 1 \leq k \leq n)$ contains at most three repetitions of any particular value.

These fractions ($z_k$) constitute an accurate set of approximations to the sequence $2^n\alpha \mod 1$ of shifted fractions of $\alpha$. In fact, by examining (20) it can be readily seen that for all $n \geq 3$,

$$
|2^n\alpha \mod 1 - z_n| < \frac{1}{96n}.
$$

(22)

To establish that $\alpha$ is 2-normal via Lemma 1, we seek an upper bound for $2^m A(\alpha, y, n, m)/n$. A binary sequence $y$ out to some length $m$, translated to a subset of the real unit interval, is $[r, s)$, where $r = 0.y_1 y_2 y_3 \ldots y_m$, and $s$ is the next largest binary fraction of length $m$, so that $s - r = 2^{-m}$. Observe that $A(\alpha, y, n, m)$ is equal to the number of those $j$ between 0 and $n - 1$ for which $2^j\alpha \mod 1 \in [r, s)$. Also observe, in view of (22), that if $2^j\alpha \mod 1 \in [r, s)$, then $z_j \in [r - 1/(96j), s + 1/(96j))$.

Let $n$ be any integer greater than $2^m$, and let $3^p$ denote the largest power of 3 less than or equal to $n$, so that $3^p \leq n < 3^{p+1}$. Now note that for $j \geq 2^m$, we have $[r - 1/(96j), s + 1/(96j)) \subset [r - 2^{-m-1}, s + 2^{-m-1})$. Since the length of this latter interval is $2^{-m-1}$, the number of multiples of $1/3^p$ that it contains cannot exceed $[3^p 2^{-m-1}] + 1$. Thus there can be at most three times this many $j$’s less than $n$ for
which $z_j \in [r - 2^{-m-1}, s + 2^{-m-1})$. Therefore we can write

$$\frac{2^m A(\alpha, y, n, m)}{n} = \frac{2^m \#_{0 \leq j < n} (2^i \alpha \mod 1 \in [r, s])}{n} \leq \frac{2^m \left[ 2^m + \#_{2^m \leq j < n} (z_j \in [r - 2^{-m-1}, s + 2^{-m-1}]) \right]}{n} \leq \frac{2^m \left[ 2^m + 3(3p2^{-m-1} + 1) \right]}{n} < 8.$$

We have shown that for all $y \in [0, 1)$ and all $m > 0$,

$$\limsup_{n \to \infty} \frac{2^m A(\alpha, y, n, m)}{n} \leq 8,$$

so by Lemma 1, $\alpha$ is 2-normal. \hfill QED

**Proof of Theorem 6:** For every coprime pair of integers $(b, c)$ with $b \geq 1$ and $c \geq 1$, the constant $\alpha_{b,c} = \sum_{m=0}^{\infty} 1/(c^m b^c m)$ is $b$-normal.

In this more general case, we can write

$$b^n \alpha_{b,c} \mod 1 = \left( \sum_{m=0}^{\lfloor \log_c n \rfloor} \frac{b^n - c^n \mod c^m}{c^m} \right) \mod 1 + \sum_{m=\lfloor \log_c n \rfloor + 1}^{\infty} \frac{b^n - c^n}{c^m}. \quad (24)$$

As before, note that the first expression can be generated by means of the recursion $z_0 = 0$ and, for $n \geq 1$, $z_n = (bz_{n-1} + r_n) \mod 1$, where $r_n = 1/n$ if $n = c^k$ for some integer $k$, and zero otherwise. When $c$ is prime, one always obtains a sequence of fractions quite similar to the sequence above (21). When $c$ is composite, though, there is slight complication in that some powers of $1/c^p$ do not appear. For example, consider the case $b = 3$ and $c = 4$. Then the first few members of the $z$ sequence are given as follows:

$$\begin{align*}
0, & \ 0, \ 0, \\
\frac{1}{4}, & \ \frac{3}{4}, \ \text{(repeated 6 times)} \\
\frac{5}{16}, & \ \frac{15}{16}, \ \frac{13}{16}, \ \frac{7}{16}, \ \text{(repeated 12 times)}, \\
\frac{21}{64}, & \ \frac{63}{64}, \ \frac{61}{64}, \ \frac{55}{64}, \ \frac{37}{64}, \ \frac{47}{64}, \ \frac{13}{64}, \ \frac{39}{64}, \ \frac{53}{64}, \ \frac{31}{64}, \ \frac{29}{64}, \ \frac{23}{64}, \ \frac{5}{64}, \ \frac{15}{64}, \ \frac{45}{64}, \ \frac{7}{64}, \\
\frac{61}{64}, & \ \frac{63}{64}, \ \frac{61}{64}, \ \frac{55}{64}, \ \frac{37}{64}, \ \frac{47}{64}, \ \frac{13}{64}, \ \frac{39}{64}, \ \frac{53}{64}, \ \frac{31}{64}, \ \frac{29}{64}, \ \frac{23}{64}, \ \frac{5}{64}, \ \frac{15}{64}, \ \frac{45}{64}, \ \frac{7}{64}, \\
\text{(repeated 12 times), etc.} & \end{align*} \quad (25)$$

24
Note here that the fraction $1/2$ is omitted in the first set, the fractions $1/8, 3/8, 5/8, 7/8$ are omitted in the second set, and the fractions with 32 in the denominators are omitted in the third set. Nonetheless, this critical property holds, both in this particular case and in general, so long as $b \geq 2$ and $c \geq 2$ are coprime: if $n < c^{p+1}$ then $z_n$ is a multiple of $1/c^p$, and furthermore the set $(z_k, 1 \leq k \leq n)$ contains at most $t$ repetitions of any particular value, where the integer $t$ depends only on $(b, c)$. For the case $(2, 3)$, the repetition factor $t = 3$. For the case $(3, 4)$, $t = 12$.

As before, these fractions $(z_k)$ constitute an accurate set of approximations to the sequence $b^a \alpha_{b,c}$ mod 1 of shifted fractions of $\alpha_{b,c}$. In fact, by examining (24) it can be readily seen that for all $(b, c)$ as above and all $n \geq c$,

$$|b^a \alpha_{b,c} \text{ mod } 1 - z_n| < \frac{1}{9n}$$

(and in most cases is much smaller than this).

To establish that $\alpha_{b,c}$ is $b$-normal via Lemma 1, we seek an upper bound for $b^m A(\alpha_{b,c}, y, n, m)/n$. A binary sequence $y$ out to some length $m$, translated to a subset of the real unit interval, is $[r, s)$, where $r = 0.y_1 y_2 y_3 \ldots y_m$, and $s$ is the next largest base-$b$ fraction of length $m$, so that $s - r = b^{-m}$. Observe that $A(\alpha_{b,c}, y, n, m)$ is equal to the number of those $j$ between 0 and $n - 1$ for which $b^j \alpha_{b,c} \text{ mod } 1 \in [r, s)$. Also observe, in view of (26), that if $b^j \alpha \text{ mod } 1 \in [r, s)$, then $z_j \in [r - 1/(9j), s + 1/(9j))$.

Let $n$ be any integer greater than $b^{2m}$, and let $c^p$ denote the largest power of $c$ less than or equal to $n$, so that $c^p \leq n < c^{p+1}$. Now note that for $j \geq b^m$, we have $[r - 1/(9j), s + 1/(9j)) \subset [r - b^{-m-1}, s + b^{-m-1})$. Since the length of this latter interval is no greater than $2b^{-m}$, the number of multiples of $1/c^p$ that it contains cannot exceed $[2c^p b^{-m}] + 1$. Thus there can be at most $t$ times this many $j$’s less than $n$ for which $z_j \in [r - b^{-m-1}, s + b^{-m-1})$. Therefore we can write

$$\frac{b^m A(\alpha_{b,c}, y, n, m)}{n} = \frac{b^m \#_{0 \leq j < n}(b^j \alpha_{b,c} \text{ mod } 1 \in [r, s))}{n} \leq \frac{b^m [b^m + \#_{b^m \leq j < n}(z_j \in [r - b^{-m-1}, s + b^{-m-1})]}}{n} \leq \frac{b^m [b^m + t(2c^p b^{-m} + 1)]}{n} < 2t + 2,$$

where $t$ is the repetition factor for $(b, c)$, mentioned above. For a fixed pair of integers $(b, c)$, we have shown that for all $y \in [0, 1)$ and all $m > 0$,

$$\limsup_{n \to \infty} \frac{b^m A(\alpha_{b,c}, y, n, m)}{n} \leq 2t + 2,$$

(27)
so by Lemma 1, $\alpha_{b,c}$ is $b$-normal.

QED

**Proof of Theorem 7:** $\alpha_{2,3}$ is not 6-normal.

Let $Q_m$ be the base-6 expansion of $\alpha_{2,3}$ immediately following position $3^m$ (i.e., after the “decimal” point has been shifted to the right $3^m$ digits). We can write

$$Q_m = 6^{3^m} \alpha_{2,3} \mod 1 = \left( \sum_{k=0}^{m} 3^{3^m-k} \cdot 2^{3^m-3^k} \right) \mod 1 + \sum_{k=m+1}^{\infty} 3^{3^m-k} \cdot 2^{3^m-3^k}. \quad (28)$$

The first portion of this expression is zero, since all terms in the summation are integers. The small second portion is very accurately approximated by the first term of the series, namely $(3/4)^{3^m} / 3^{m+1}$. In fact, for all $m \geq 1$,

$$\left( \frac{3}{4} \right)^{3^m} < Q_m < \left( \frac{3}{4} \right)^{3^m} \left( 1 + 2 \cdot 10^{-6} \right). \quad (29)$$

Let $Z_m = \lfloor \log_6 1/Q_m \rfloor$ be the number of zeroes in the base-6 expansion of $\alpha$ that immediately follow position $3^m$. Then for all $m \geq 1$, (29) can be rewritten

$$3^m \log_6 \left( \frac{4}{3} \right) + (m + 1) \log_6 3 - 2 < Z_m < 3^m \log_6 \left( \frac{4}{3} \right) + (m + 1) \log_6 3. \quad (30)$$

Now let $F_m$ be the fraction of zeroes in the base-6 expansion of $\alpha$ up to position $3^m + Z_m$ (i.e., up to the end of the block of zeroes that immediately follows position $3^m$). Clearly

$$F_m > \frac{\sum_{k=1}^{m} Z_k}{3^m + Z_m}, \quad (31)$$

since the numerator only counts zeroes in the long stretches. The summation in the numerator satisfies, for all sufficiently large $m$,

$$\sum_{k=1}^{m} Z_k > \frac{3}{2} \left( 3^m - \frac{1}{3} \right) \log_6 \left( \frac{4}{3} \right) + \frac{m(m + 3)}{2} \log_6 3 - 2m$$

$$> \frac{3}{2} \cdot 3^m \log_6 \left( \frac{4}{3} \right) - \frac{1}{2} \log_6 \left( \frac{4}{3} \right) - 2m. \quad (32)$$
Now given any $\varepsilon > 0$, we can write, for all sufficiently large $m$,

\[
F_m > \frac{\frac{3}{2} \cdot 3^m \log_6 \left(\frac{4}{3}\right) - \frac{1}{2} \log_6 \left(\frac{4}{3}\right) - 2m}{3^m + 3^m \log_6 \left(\frac{4}{3}\right) + (m + 1) \log_6 3}
\]

\[
= \frac{\frac{3}{2} \log_6 \left(\frac{4}{3}\right) - \frac{1}{2m} \left(\frac{1}{2} \log_6 \left(\frac{4}{3}\right) + 2\right)}{1 + \log_6 \left(\frac{4}{3}\right) + \frac{(m + 1) \log_6 3}{3^m}}
\]

\[
\geq \frac{\frac{3}{2} \log_6 \left(\frac{4}{3}\right) - \varepsilon}{1 + \log_6 \left(\frac{4}{3}\right) + \varepsilon} \geq \frac{1}{2} \log_2 \left(\frac{4}{3}\right) - 2\varepsilon.
\] (33)

But $\beta = \frac{1}{2} \log_2 (4/3)$ (which has numerical value $0.2075187496 \ldots$) is clearly greater than $1/6$, since $(4/3)^3 = 64/27 > 2$. This means that infinitely often (namely, whenever $n = 3^m + Z_m$) the fraction of zeroes in the base-6 expansion of $\alpha$ up to position $n$ exceeds $\frac{1}{2}(1/6 + \beta) > 1/6$. Thus $\alpha$ is not 6-normal.  

QED

**Proof of Theorem 8:** Given co-prime integers $b \geq 2$ and $c \geq 2$, the constant $\alpha_{b,c} = \sum_{k \geq 0} 1/(c^k b^k)$ is not $bc$-normal.

Let $Q_m(b, c)$ be the base-$bc$ expansion of $\alpha_{b,c}$ immediately following position $c^m$. Then

\[
Q_m(b, c) = (bc)c^m \alpha_{b,c} \mod 1
\]

\[
= \left( \sum_{k=0}^{m} c^{m-k} b^m c^k \right) \mod 1 + \sum_{k=m+1}^{\infty} c^{m-k} b^m c^k.
\] (34)

As above, the first portion of this expression is zero, since all terms in the summation are integers, and the second portion is very accurately approximated by the first term of the series, namely $\left[\frac{c}{b(c-1)}\right]c^m/c^{m+1}$. In fact, for any choice of $b$ and $c$ as above, and for all $m \geq 1$,

\[
\frac{1}{c^{m+1}} \left[\frac{c}{b(c-1)}\right]c^m < Q_m(b, c) < \frac{1}{c^{m+1}} \left[\frac{c}{b(c-1)}\right]c^m \cdot (1 + 1/10).
\] (35)

Let $Z_m(b, c) = \lfloor \log_{bc} 1/Q_m(b, c) \rfloor$ be the number of zeroes that immediately follow position $c^m$. Then for all $m \geq 1$, (35) can be rewritten as

\[
c^m \log_{bc} \left[\frac{b(c-1)}{c}\right] + (m + 1) \log_{bc} c - 2
\]

\[
< Z_m(b, c) < c^m \log_{bc} \left[\frac{b(c-1)}{c}\right] + (m + 1) \log_{bc} c.
\] (36)
Now let $F_m(b,c)$ be the fraction of zeroes up to position $c^m + Z_m(b,c)$. Clearly

$$F_m(b,c) > \frac{\sum_{k=1}^{m} Z_k(b,c)}{c^m + Z_m(b,c)},$$

(37)

since the numerator only counts zeroes in the long stretches. The summation in the numerator of $F_m(b,c)$ satisfies

$$\sum_{k=1}^{m} Z_k(b,c) > \frac{c}{c-1} \left( c^m - \frac{1}{c} \right) \log_{bc} \left[ \frac{b(c-1)}{c} \right] + \frac{m(m+3)}{2} \log_{bc} c - 2m$$

> \frac{c^{m+1}}{c-1} \log_{bc} \left[ \frac{b(c-1)}{c} \right] - \frac{1}{c-1} \log_{bc} \left[ \frac{b(c-1)}{c} \right] - 2m. \quad (38)

Thus given any $\varepsilon > 0$, we can write, for all sufficiently large $m$,

$$F_m(b,c) > \frac{c^{m+1}}{c-1} \log_{bc} \left[ \frac{b(c-1)}{c} \right] - \frac{1}{c-1} \log_{bc} \left[ \frac{b(c-1)}{c} \right] - 2m$$

> \frac{c^m + c^m \log_{bc} \left( \frac{b(c-1)}{c} \right) + (m+1) \log_{bc} c}{1 + \log_{bc} \left[ \frac{b(c-1)}{c} \right]} + \frac{(m+1) \log_{bc} c}{c^m}$$

$$\geq \frac{c}{c-1} \log_{bc} \left[ \frac{b(c-1)}{c} \right] - \varepsilon$$

$$\geq \frac{c}{c-1} \log_{bc} \left[ \frac{b(c-1)}{c} \right] + \varepsilon$$

$$\geq \frac{c}{c-1} \log_{bc} \left[ \frac{b(c-1)}{c} \right] - 2\varepsilon.$$  

$$= T(b,c) - 2\varepsilon, \quad (40)$$

where

$$T(b,c) = \frac{c}{c-1} \cdot \log_{bc} \left[ \frac{b(c-1)}{c} \right]. \quad (41)$$

To establish the desired result that $T(b,c) > 1/(bc)$, first note that

$$T(b,c) > \frac{1}{2} \log_{bc} \left[ \frac{b(c-1)}{c} \right] \geq \frac{1}{2} \log_{bc} \left( \frac{b}{2} \right). \quad (42)$$
Raise $bc$ to the power of the right-hand side, and also to the power $1/(bc)$. Then it suffices to demonstrate that

$$\frac{b}{2} > \left[(bc)^{1/(bc)}\right]^2. \tag{43}$$

The right-hand side is bounded above by $(e^{1/e})^2 = 2.0870652286\ldots$. Thus this inequality is clearly satisfied whenever $b \geq 5$.

If we also presume that $c \geq 5$, then by examining the middle of (42) it suffices to demonstrate that

$$\frac{1}{2} \log_{bc} \frac{4b}{5} > \frac{1}{bc} \tag{44}$$

or

$$\frac{4b}{5} > \left(e^{1/e}\right)^2. \tag{45}$$

But this is clearly satisfied whenever $b \geq 3$. For the case $b = 2$ and $c \geq 5$, we can write

$$T(b, c) = \frac{c}{c - 1} \cdot \frac{\log_{2c} \left[\frac{2(c-1)}{c}\right]}{1 + \log_{2c} \left[\frac{2(c-1)}{c}\right]} \geq \frac{\log_{2c} \left[\frac{2(c-1)}{c}\right]}{1 + \log_{10} 2}, \tag{46}$$

so by similar reasoning it suffices to demonstrate that

$$\frac{2(c-1)}{c} > (e^{1/e})^{1+\log_{10} 2} = 1.6138492883\ldots. \tag{47}$$

But this is clearly satisfied whenever $c \geq 6$.

The five remaining cases, namely $(2, 3), (2, 5), (3, 2), (3, 4), (4, 3)$, are easily verified by explicitly computing numerical values of $T(b, c)$ using (41). As it turns out, the simple case that we worked out in detail above, namely $b = 2$ and $c = 3$, is the worst case, in the sense that for all other $(b, c)$, the fraction $T(b, c)$ exceeds the natural frequency $1/(bc)$ by greater margins.

QED

The proofs of Theorems 7 and 8 above are adapted from [1].
