LATERAL LINE AND OLFACTORY SENSORY SYSTEMS IN THE BIOLOGY OF THE BANDED KOKOPU *Galaxias fasciatus*

By Cindy F. Baker

Abstract

The banded kokopu, *Galaxias fasciatus*, is one of the five diadromous galaxiid species, which form the basis of New Zealand's recreational and commercial whitebait fishery. With a continual decline in the abundance of whitebait species, additional knowledge on factors affecting galaxiid populations is crucial. This thesis examines the use of olfactory and lateral line sensory systems in the biology of banded kokopu as both adults and juveniles (whitebait).

The feeding biology of banded kokopu adults was investigated through olfactory source localisation. In the presence of a 2 cm s^{-1} current flow, fish used both olfaction and the superficial neuromasts of the lateral line system to locate the food source. A physical block of one olfactory nostril did not affect the olfactory search strategy employed by banded kokopu.

Banded kokopu whitebait were tested for their response to adult galaxiid odours. Migratory whitebait exhibited a species-specific attraction to adult conspecifics. There was no response shown to odours from adults of other galaxiid species, the inanga (*G. maculatus*) or koaro (*G. brevipinnis*) at any concentration tested. This pheromonal attraction may play an important role in habitat selection during migration.

The effect of poor water quality on sensory performance was also investigated. After exposure to $0.5 \mu\text{g Cd}^{2+} \text{ l}^{-1}$ for 48 hours, the attraction to adult pheromones had been eliminated, indicating this level of cadmium exposure had impaired olfactory function. The lateral line system was not blocked until a concentration of $2 \mu\text{g Cd}^{2+} \text{ l}^{-1}$. Whitebait were also tested for a preference/avoidance response at $2 \mu\text{g Cd}^{2+} \text{ l}^{-1}$ and showed neither a preference for, or an avoidance of, a concentration which would disable both the lateral line and olfactory sensory systems. This concentration is within the current water quality criteria for protection of aquatic life. The disabling of these sensory systems may render migratory cues undetectable, affecting habitat selection by whitebait, which may ultimately affect the distribution of banded kokopu populations.

This thesis furthers our understanding of the mechanisms of migration and feeding in banded kokopu. The use of both the lateral line and olfactory sensory systems in the location of food odours by adult fish provides the first demonstration of the use of the lateral line system in olfactory source localisation in fish. The importance of water quality in the detection of possible migratory cues has been illustrated with cadmium, where inhibition of sensory systems rendered pheromonal cues undetectable. The pheromonal attraction exhibited by whitebait to adults provides a possible migratory cue used by whitebait in locating habitat for colonisation. The identification of a migratory cue could help in the conservation of banded kokopu populations and in the management of New Zealand's whitebait fishery.

ACKNOWLEDGMENTS

I would firstly like to thank my supervisor John Montgomery for his continued guidance and support. Thank you to the University of Auckland for providing the Doctoral Scholarship which enabled me to complete my doctorate and to John Macdonald for supplying me with office space, a computer and reading my thesis draft. I am also indebted to Athol Adams, who provided the experimental whitebait.

A special thank you to Vivian, Adrian and Iain of Graphics, who catered to my every whim, providing service with a smile and pleasant conversation. Thank you to Percy, Brian and Rabendra for readily supplying me with tools and performing odd-jobs on request.

A big thank you to Matthew Halstead for his continued friendship plus statistical and computer support. To Serena, thank you for your friendship and enduring sharing a room with me. A special thank you to Lance for the many late night fishing expeditions he suffered and for the technical support in creating experimental setups.

Last but not least I wish to thank my parents for the endless generosity and support they have shown me throughout my education.

LIST OF FIGURES

1.1	The banded kokopu, <i>Galaxias fasciatus</i>	4
2.1	The experimental apparatus used to examine odour search behaviour in <i>G. fasciatus</i>	12
2.2	Representative search tracks of normal <i>G. fasciatus</i> within an odour plume	18
2.3	The proportion of heading and turning angles observed for normal <i>G. fasciatus</i> whilst searching inside the odour plume..	19
2.4	The proportion of heading angles observed for normal <i>G. fasciatus</i> whilst searching outside of the odour plume in the presence of a 2 cm s^{-1} current flow	20
2.5	Uniform probability plots	21
2.6	Scanning electron micrographs of a section from the infraorbital region of <i>G. fasciatus</i>	24
2.7	Representative search tracks of <i>G. fasciatus</i> without superficial neuromasts within an odour plume	25
2.8	The proportion of heading and turning angles observed for <i>G. fasciatus</i> without superficial neuromasts whilst searching inside the odour plume	26
2.9	Representative search tracks of <i>G. fasciatus</i> with their right nostril plugged within an odour plume	29
2.10	The proportion of heading and turning angles observed for <i>G. fasciatus</i> with their right nostril plugged whilst searching within the odour plume	30
3.1	The experimental choice chamber	45
3.2	Mean number of <i>G. fasciatus</i> present in each chamber when subjected to different volumes of odour water from each galaxiid species	50
4.1	Housing tank and experimental apparatus used for the rheotaxis experiments	65

4.2	Mean number of <i>G. fasciatus</i> present in each chamber when subjected to adult pheromones after different levels of cadmium exposure	69
4.3	Mean number of <i>G. fasciatus</i> present in each chamber when subjected to adult pheromones after recovery from cadmium exposure	71
4.4	Mean number of <i>G. fasciatus</i> exhibiting rheotaxis under different experimental treatments	72
4.5	The recovery rate of rheotaxis in <i>G. fasciatus</i> whitebait exposed to $2 \mu\text{g Cd}^{2+} \text{ l}^{-1}$ for 48 hours	73
4.6	Mean number of <i>G. fasciatus</i> present in each chamber when given the choice between clean freshwater and water containing $2 \mu\text{g Cd}^{2+} \text{ l}^{-1}$	76

LIST OF TABLES

2.1	The average heading and turning angles for each treatment group of <i>G. fasciatus</i> in still water and the presence of a 2 cm s ⁻¹ current flow whilst searching inside the odour plume	17
2.2	The average heading angle of normal <i>G. fasciatus</i> outside of the odour plume in the presence of a 2 cm s ⁻¹ current flow	20
2.3	The average time taken to reach the odour source for each treatment group of <i>G. fasciatus</i> in still water and the presence of a 2 cm s ⁻¹ current flow	23
2.4	The average search velocity inside and outside of the odour plume for each treatment group of <i>G. fasciatus</i> in still water and the presence of a 2 cm s ⁻¹ current flow.	28
2.5	The proportion of left and right turns made by normal and right nose plugged <i>G. fasciatus</i> in still water	31
2.6	The average swim velocity in the absence of an odour plume for each treatment group of <i>G. fasciatus</i> in still water and the presence of a 2 cm s ⁻¹ current flow.	32
3.1	Chi-square analysis of the mean number of <i>G. fasciatus</i> present in each chamber under different experimental conditions	51
