## ACKNOWLEDGMENTS

---

There are a large number of people I would like to thank, without whom this work would not have been possible:

First and foremost, my supervisor Associate-Professor Richard Gardner, who provided encouragement and advice throughout this work and spent many hours editing and improving this thesis and my manuscripts.

Thanks also go to many of the other faculty members in the School of Biological Sciences, in particular Professor Dick Matthews, my co-supervisor Professor Dick Bellamy, and to all the others who provided information and advice.

To all the PMB members past and present, in particular to Jeannette, Susan, Keith and Colin, and to my fellow aluminium workers and wine drinkers - you have all helped to make the last few years enjoyable.

Beryl Davy, for her expertise and patience at showing me how to section my plant tissue.

To the people in the ARB group who helped me with the protein sections of this work, in particular Judy and John for advice about the protein fusions, and Jan for advice on westerns.

To all the computer experts out there who helped solve all my crises at short notice, in particular Dave, Terry and Moreland.

Professor Paul Williams for the use of the densitometer (and Susan for showing me how to use it).

To Bart, Susan and Ross for all the time and energy they spent in proof-reading.

To all the organisations who provided financial support, both for my stipend and for the trip to Cold Spring Harbor.

To my family and friends who provided welcome distractions when I needed a break.

And finally, to Bart, who helped immeasurably with this thesis, and was there for me throughout all the toughest times of the last few years.

## ABSTRACT

---

Aluminium (Al) toxicity to plants is a significant problem, limiting agricultural production in up to 40% of the world's arable soils. In spite of a large amount of research, there is still no consensus on the physiological mechanisms of Al toxicity in plants. In addition, very little is known about the molecular response of plants to Al stress. This body of research was aimed at identifying the changes in gene expression that occurred in the root tips of plants that had been stressed with Al.

A cDNA library made from the root tips of Al-treated wheat (*Triticum aestivum* L., cultivar Warigal) plants was differentially screened to identify clones whose expression was induced by Al stress. Seven cDNA clones, representing five different genes were identified as being induced in the presence of Al. Initial sequencing and northern analysis revealed that none of the clones isolated were full-length, and that some contained multiple cloning adaptors at their 5' ends. A new cDNA library was then constructed from the root tips of Al-treated Warigal plants, and homologues to each of the original five genes were isolated. These five clones were named wali1 to wali5 (for wheat aluminium induced).

Northern analysis showed that wali1, -3 and -5 were induced 24 to 96 h after Al treatment, and their expression declined when the Al was removed. wali4 had a similar pattern of expression with a transient increase in expression also observed after 0.5 h of Al stress. Each of these four genes was induced by inhibitory concentrations of Al in two wheat cultivars - Warigal, an Al-sensitive cultivar, and Waalt, an Al-tolerant cultivar, - and also in two inbred lines of wheat, RR (Al-tolerant) and SS (Al-sensitive). The fifth gene (wali2) had a bimodal pattern of induction, and was induced by Al only in the Al-sensitive Warigal and the Al-tolerant RR.

The nucleotide sequence of each of the wali clones was determined, and the databases were searched for homologous sequences. wali1 was found to be homologous to a group of metallothionein-like proteins (MLPs) from plants, and wali4 was homologous to phenylalanine ammonia-lyase (PAL). wali3 and wali5 encode related, cysteine-rich proteins with homology to Bowman-Birk proteinase inhibitors, and wali2 encodes a novel protein with a repeating motif of cysteine amino acids.

The induction of the wali genes was investigated in response to a number of other stresses through northern analysis. The expression of wali1, -3, -4 and -5 was induced in root tips of wheat after 2 d treatments with toxic levels of all other metals tested (Cd, Fe, Zn, Cu, Ga, In and La). The expression levels of wali1, -3, -4, and -5 also increased in the root tips of plants grown in the presence of low levels of Ca (10  $\mu$ M). The transcript levels of wali1, -3 and -5 increased in wounded leaf and root tissue, whereas the transcript levels of wali4 increased only in wounded leaves. The expression of

wali2 was greatly reduced by low concentrations of Ca, and showed no induction, or a variable response with most of the other treatments.

The site of expression of wali1, -2, -3 and -5 in root tips (and wali1 also in leaf tissue) was identified using *in situ* hybridisation. wali1 was expressed predominantly in the meristematic tissue of the root tip, while wali3 and wali5 were expressed predominantly in the cortical tissue of the root. wali2 expression was detected primarily in the epidermis and root cap. Some changes in the site of expression of these genes were evident in the roots of Al-treated plants. In leaf tissue, wali1 expression was found in the mesophyll layer of cells.

The coding sequences for wali1, -2, -3 and -5 were each cloned into the bacterial expression vector pGEX-2T. The resultant fusion proteins between glutathione S-transferase (GST) and the walis were then successfully purified from *E. coli*. Antibodies were made to the wali1-GST fusion protein and purified by immunoaffinity chromatography. However, when used in western analysis, no specific bands corresponding to the native wali1 protein were identified. The wali2-GST protein was used in a south-western procedure to determine if the protein was capable of binding DNA, but no DNA binding to this protein was detected under the conditions tested. The wali3 and wali5 fusion proteins were tested in proteinase inhibitor assays, where no inhibition of either trypsin or chymotrypsin was detected. It is possible that the native wali3 and wali5 proteins may not function as proteinase inhibitors, or that the lack of activity detected for the fusion proteins may be due to incorrect folding or processing in the bacterial system.

This research constitutes the first identification of plant genes whose expression is increased by Al stress. The genes identified are also induced in response to other environmental and nutrient stresses, indicating that they form part of the plant's general response to stress.

## ABBREVIATIONS

---

Standard SI units, chemical abbreviations and the one and three letter codes for amino acids and nucleotides have been used throughout this thesis, as well as the abbreviations that follow:

|                 |   |
|-----------------|---|
| aa              | amino acid(s)   |
| ATP             | adenosine triphosphate  |
| bp              | base pair(s)  |
| BSA             | bovine serum albumin  |
| CNBr            | cyanogen bromide  |
| cv              | cultivar  |
| C-terminus      | carboxy-terminus (of a polypeptide)                               |
| dCTP            | deoxycytidine-5'-triphosphate                                     |
| DIG             | digoxygenin   |
| DMDC            | dimethyl-dicarbonate  |
| DNA             | deoxyribonucleic acid   |
| DNAse           | deoxyribonuclease I   |
| dNTP            | deoxyribonucleotide triphosphate                                  |
| DMSO            | dimethyl sulphoxide   |
| DTT             | dithiothreitol  |
| EDTA            | disodium salt of ethylenediaminetetraacetic acid                  |

| N-terminus      | amino-terminus (of a polypeptide)                                 |
| OD <sub>x</sub> | optical density - the absorbance measured at a wavelength of x nm |
| ORF             | open reading frame  |
| PAL             | phenylalanine ammonia-lyase                                       |
| PCR             | polymerase chain reaction   |
| pfu             | plaque forming units  |
| PIPES           | piperazine-N-N'-bis (2-ethane sulfonic acid)                      |

|        |   |
|--------|---|
| PVDF   | polyvinylidene difluoride                                       |
| PVP    | polyvinylpyrrolidone  |
| RH     | relative humidity   |
| RNAse  | ribonuclease  |
| SDS    | sodium dodecyl sulphate   |
| SE     | standard error  |
| Tris   | Tris(hydroxymethyl)-aminomethane                                |
| UV     | ultraviolet (light)   |
| v/v    | volume to volume (with respect to the percentage of a solution) |
| X-Gal  | 5-bromo-4-chloro-3-indolyl- $\beta$ -D-thiogalactoside          |
| X-phos | 5-bromo-4-chloro-3-indolyl-phosphate                            |
