ABSTRACT

Given a linear regression model $y = X\beta + \epsilon$, where ϵ has a multivariate normal distribution $N(\mu, \Sigma)$ consequences of the erroneous assumption that ϵ is distributed as $N(\mu, I)$ are considered. For a general linear hypothesis concerning the parameters β , in a general model the distribution of the statistic to test the hypothesis, derived under the erroneous assumption is studied. Particular linear hypotheses concerning particular linear models are investigated so as to describe the effects of various patterns of serial correlation on the test statistics arising from these hypotheses. Attention is specially paid to the models of one- and two- way analysis of variance.

ACKNOWLEDGEMENTS

My gratitude is due to many people for the help and advice they have given to me while I have been working on this thesis.

Particular thanks must go first to my supervisor, Professor G.A.F. Seber for his ever present consideration and sympathetic encouragement, both at the University of Otago and the University of Auckland. To Professor A.J. Scott thanks are also due for his constant cheerful interest in the progress of the thesis.
