THE ROLE OF THE CRYSTALLINE LENS IN AMETROPIA

Rolene Scott

A thesis submitted to the University of Auckland
for the degree of Doctor of Philosophy in Optometry

Auckland 1993

ABSTRACT

When examining the dimensions of the crystalline lens, it is found that some may vary with different types of refractive error. The effects of several of these variations on refractive error are investigated in this thesis.

To examine whether lens thickness was significantly different in youth-onset myopes compared with emmetropes, a structural model was developed and tested. No substantial difference was found between the two groups. In both groups of eyes, increased lens thickness was found to contribute significantly to the refractive state of the eye; a thicker lens effectively being a stronger lens.

The crystalline lens may play a different role in early adult-onset myopia which develops after normal growth has ceased compared to its role in youth-onset myopia. Cross-sectional data from early adult-onset myopes, youth-onset myopes and emmetropes were evaluated to determine whether lens thickness differed among the refractive error groups. No significant differences were found.

However, some early adult-onset myopes and youth-onset myopes were re-evaluated three years after the initial data were collected and a significant increase in mean lens thickness

was found in the group of early adult-onset myopes. No significant mean lens thickness increase occurred in the group of youth-onset myopes.

To evaluate further the contribution of the crystalline lens dimensions to the refractive state of the eye, radii of curvature and lens thicknesses of a group of anisometropes were examined. Radii were found not to be consistently flatter or steeper in the relatively more myopic eye compared with the relatively less myopic eye and there was also no significant difference between mean lens thickness of the relatively more myopic eye compared to mean lens thickness of the relatively less myopic eye.

Crystalline lens thickness and radii of curvature were therefore found to play only a minor role in refractive error development. Deeper vitreous chambers and steeper corneal curvatures were found to be the major contributors to myopia.

AUTHOR'S STATEMENT

The investigations reported in this thesis are entirely my own work except where assistance is specifically acknowledged.

Rolene Scott

ACKNOWLEDGEMENTS

This research work was conducted within the Department of Optometry, University of Auckland. The studies were supervised by Dr M K Yap (Senior Lecturer) and Prof L F Garner (Head of Department). Their contribution to the thesis is much appreciated, as is the contribution of partial financial support for the research by the New Zealand Optometric Vision Research Foundation.

I wish to thank Prof T Grosvenor (Visiting Professor) whose guidance and patience throughout the data collection period, and especially in the preparation of the manuscript for the "Structural Model for Emmetropic and Myopic Eyes", were most helpful. I would also like to acknowledge the staff of the Department of Optometry for their help in setting up the equipment, Scott Shirley for taking the photographs, and the subjects who participated in the various studies.

I am most grateful to Don for his endless help and support which made this thesis possible.

PREFACE

This thesis includes work which has already been published in the following papers:
