We have compared the expression of CD2, CD11a/CD18, CD44, and CD58 on $\alpha\beta$ and $\gamma\delta$ T cells emigrating from the fetal and postnatal thymus. We report that both $\gamma\delta$ and the CD4⁺CD8⁻ and CD4⁻CD8⁺ subsets of $\alpha\beta$ T cells express mature levels of the adhesion molecules CD11a/CD18, CD44, and CD58 upon emigration from the thymus. Whereas CD44 is up-regulated on $\gamma\delta$ ⁺ thymocytes prior to export, down-regulation of both CD11a/CD18 and CD58 occurs prior to emigration from the thymus, suggesting that down-regulation of these molecules may be a final maturational step taken by developing $\gamma\delta$ T cells before their export from the thymus. In contrast, there is continued up-regulation of CD2 on $\gamma\delta$ and $\alpha\beta$ T cells upon emigration from the thymus and as they move into the mature peripheral T-cell pool. There was also a marked reduction in the number of CD2⁺ $\gamma\delta$ T cells exported during fetal development that was associated with a marked reduction in the percentage of CD2⁺ $\gamma\delta$ thymocytes exported. The postthymic maturation of CD2 and the other changes in adhesion-molecule expression appear to be independent of extrinsic antigen, as the same changes were observed in the antigen-free environment of the fetus as in the postnatal lamb, which has been exposed to extrinsic antigen. It thus appears that these changes in adhesion-molecule expression are as a result of the normal maturation pathway from a developing thymocyte to a mature peripheral T cell.

KEYWORDS: Thymic emigrants, CD2, CD11a/18, CD44, CD58, fetal, $\gamma\delta$ T cells.

INTRODUCTION

Adhesion molecules are crucial for mature T-cell function and they have also been implicated in T-cell ontogeny and differentiation (Hogg and Landis, 1993; Janeway Jr. and Golstein, 1993). Studies on human thymocytes have suggested that interaction of the adhesion molecule CD2 with its ligand CD58 is necessary for interleukin-2-receptor expression, and hence T-cell expansion, prior to surface CD3 and TCR expression (Reinherz, 1985). In addition, studies using murine fetal thymic organ cultures and transgenic mice have demonstrated a potential role for the adhesion molecule, CD11a/CD18 in $\alpha\beta$ T-cell differentiation (Fine and Kruisbeek, 1991) and negative selection (Carlow et al.,

1992). The addition of anti-CD11a/CD18 or anti-ICAM-1 antibodies markedly impairs the progression of CD4⁻CD8⁻ cells to CD4⁺CD8⁺ (Fine and Kruisbeek, 1991) and deletion of CD4⁺CD8⁺ thymocytes can be inhibited by anti-CD11a/CD18 monoclonal antibodies and partially inhibited by anti-ICAM-1 monoclonal antibodies (Carlow et al., 1992). A role for such molecules on $\gamma\delta$ T cells has yet to be established.

The adhesion-molecule profile of T cells has also been linked to the naive and memory status of these cells. Naive $\alpha\beta$ T lymphocytes express low levels of adhesion molecules. Shortly after antigenic stimulation, both CD4⁺ and CD8⁺ subsets express increased levels of adhesion molecules, which may persist after the stimulated lymphocytes have reverted to the resting state, and possibly last for the life of the memory cell (Sanders et al., 1988;

*Corresponding author.

Cerottini and MacDonald, 1989; Shimizu et al., 1990). To date, little is known about the level of expression of adhesion molecules on $\gamma\delta$ T cells at different stages of activation or maturity.

Although it has been known for over 30 years that the thymus is responsible for the initial formation and maintenance of the peripheral T-cell pool (Miller, 1961, 1991), little is known about the expression of adhesion molecules on T cells as they leave the thymus, although it has been shown that murine recent thymic emigrants included both CD44⁺ and CD44⁻ cells (Kelly and Scollay, 1990). In order to understand better the regulatory mechanisms controlling adhesion-molecule expression on T cells during developmental *in vivo*, it is important to know the adhesion-molecule status of T cells immediately after their export from the thymus and preferably in situations where any changes in their expression can be isolated from the effects of antigen. Sheep provide an ideal model for these purposes. It is possible to study directly naive T cells as they leave the thymus at different stages during ontogeny and it provides an additional advantage as a model because the sheep fetus is immunologically virgin (although immunologically competent), so that adhesion-molecule expression can be examined in a situation unsullied by the effects of antigen (Pearson et al., 1976; Cahill and Trnka, 1980; Kimpton et al., 1994). Examination of $\gamma\delta$ T cells is also facilitated because sheep have an unusually high proportion of $\gamma\delta$ T cells compared with mice and humans (Hein and Dudler, 1993) and thymic export of $\gamma\delta$ T cells increases during gestation to around 40% of all emigrants at 3 months of age (Witherden et al., 1994c).

Export of T cells from the murine thymus has been studied extensively by Scollay and colleagues (Scollay et al., 1980, 1984a, 1984b; Scollay, 1982). It has been shown that in mice and other species, the thymus exports about 1% of thymocytes per day (Scollay et al., 1980; Miyasaka et al., 1988, 1990; Witherden et al., 1994c) and that there are marked changes in the export of $\alpha\beta$ and $\gamma\delta$ T cells from the thymus during fetal development and after birth (Witherden et al., 1994c). Furthermore, postthymic maturation of CD45RA and L-selectin expression on thymic emigrants, which appeared to be antigen-independent, has also been shown to occur in both fetal and postnatal animals (Witherden et al., 1994a, 1994b).

The aim of this study was to examine the expression of the adhesion molecules CD2, CD11a/CD18, CD44, and CD58 on thymic emigrants in order to compare their adhesion-molecule status with that of

thymocytes and mature peripheral T cells. Thymic emigrants, like fetal sheep peripheral T cells, are indisputably naive. An examination of adhesion-molecule expression on these cells therefore provided an opportunity to establish the phenotype of naive $\gamma\delta$ T cells and to look for antigen-independent, as well as possible antigen-driven, changes in the expression of these molecules on lymphocyte subsets after emigration from the thymus.

RESULTS

Experimental Plan

Expression of the adhesion molecules CD2, CD11a/CD18, CD44, and CD58 on thymic emigrants was investigated in five 120-day-old fetuses, four 140-day-old fetuses, and five 3-month-old lambs. Thymocytes were labeled *in situ* by direct intrathymic injection of FITC, and those cells that had migrated out of the thymus were identified as FITC⁺ lymphocytes in blood 1 hour after intrathymic injection. One hour was chosen as a time when we could be confident that thymic emigrants would express the same surface phenotype as they did when they left the thymus and was the earliest time point when sufficient emigrants could be obtained to allow accurate phenotyping. Thymic emigrants were then phenotyped for CD2, CD11a/CD18, CD44, and CD58 expression and, using two-color immunofluorescence staining, the expression of these adhesion molecules on emigrant T-cell subsets was examined. Single-cell suspensions of ovine thymocytes and PBL were also phenotyped, although single-positive CD4⁺ and CD8⁺ thymocytes were not examined.

Expression of CD2 on Thymic Emigrants: Comparison with Thymocytes and Mature T Cells

The expression of CD2 on subsets of thymocytes, thymic emigrants, and mature T cells is shown in Figs. 1 and 2. There was a marked decline in the proportion of $\gamma\delta$ emigrants expressing CD2 during fetal development, from 44% at 120 days gestation to 14% at 140 days gestation, but no further change after birth (17%, Fig. 1). This fall in the number of CD2⁺ $\gamma\delta$ ⁺ emigrants coincided with an increase in the proportion of CD2⁺ $\gamma\delta$ ⁺ thymocytes, indicating that there was a marked drop in the percentage of CD2⁺ $\gamma\delta$ ⁺

FIGURE 1. The distribution of CD2 on $\gamma\delta^+$, $CD4^+ CD8^-$, and $CD4^- CD8^+$ T-cell subsets in the thymocyte, thymic emigrant, and mature peripheral blood lymphocyte populations in fetal sheep (120 and 140 days gestation) and postnatal lambs (3 months old). The proportion of CD2⁺ thymic emigrants was determined in peripheral blood 1 hr after *in situ* labeling of the thymus with FITC. Histograms represent the mean percentages of lymphocytes stained \pm SEM.

thymocytes exported from the thymus in the late-term fetus and postnatal lamb (Fig. 1). Maturation of $\gamma\delta$ emigrants in the periphery was also associated with down-regulation of CD2 because considerably fewer $\gamma\delta$ T cells in the mature blood population expressed CD2 than did $\gamma\delta$ emigrants at all ages examined (Fig. 1).

In contrast to $\gamma\delta$ emigrants, there was no difference in the percentage of CD2⁺ $\alpha\beta$ T-cell emigrants at different ages (Fig. 1). At all three ages, a significantly higher proportion of $CD4^+ CD8^-$ and $CD4^- CD8^+$ thymic emigrants expressed CD2 than $\gamma\delta$ emigrants. The vast majority of $CD4^+ CD8^-$ cells expressed CD2 although a significant minority of around 20% of both emigrant and mature $CD4^- CD8^+$ cells were CD2⁻ (Fig. 1).

CD2 expression on $\alpha\beta$ thymocytes was not examined; however, in contrast to $\gamma\delta^+$ cells, there was very little difference in the proportion of $CD4^+ CD8^-$ or $CD4^- CD8^+$ emigrants and peripheral blood lymphocytes expressing CD2 in either the fetus or the lamb (Fig. 1). The loss of CD2 between emigrants and mature T cells thus appeared to be confined to the $\gamma\delta$ T-cell subset.

The level of CD2 expression on $\gamma\delta^+$ emigrants and peripheral blood lymphocytes is shown in Fig. 2. In all experiments, $\gamma\delta^+$ emigrants expressed CD2 at a lower level than mature $\gamma\delta^+$ peripheral blood lymphocytes (Fig. 2), but at the same level as $\gamma\delta^+$ thymocytes (data not shown). The level of CD2 expression on $CD4^+ CD8^-$ and $CD4^- CD8^+$ emigrants and peripheral blood lymphocytes is also shown in Fig. 2. Like $\gamma\delta^+$ thymic emigrants, $CD4^+ CD8^-$ and $CD4^- CD8^+$ emigrants also expressed a lower level of CD2 than the equivalent mature T-cell population.

Expression of CD11a/CD18 on Thymic Emigrants: Comparison with Peripheral Blood Lymphocytes and Thymocytes

The majority (90–100%) of fetal and lamb thymocytes, thymic emigrants, and peripheral blood lymphocytes expressed CD11a/CD18 (data not shown). The level of expression of CD11a/CD18 was very similar between emigrants and peripheral blood lymphocytes for all three subsets (Fig. 2). However, a comparison of $\gamma\delta^+$ thymocytes, thymic emigrants, and mature T cells revealed that both 140-day-old fetal (data not shown) and 3-month-old lamb $\gamma\delta^+$ thymocytes expressed a considerably higher level of CD11a/CD18 than $\gamma\delta^+$ emigrants and thus a

higher level of CD11a/CD18 than $\gamma\delta^+$ peripheral blood lymphocytes (Fig. 3).

Very little difference in the level of expression of CD11a/CD18 on $\alpha\beta$ and $\gamma\delta$ subsets was apparent except for the emergence of a small CD11a/CD18^{hi} population amongst CD4⁻CD8⁺ peripheral blood lymphocytes that appeared late in gestation and was still apparent after birth (Fig. 2). This CD11a/CD18^{hi} population was not present amongst the CD4⁺CD8⁻ or $\gamma\delta^+$ subsets or amongst any of the three subsets at 120 days gestation, nor was it detectable in any thymic emigrant population.

Expression of CD44 and CD58 on Thymic Emigrants: Comparison with Peripheral Blood Lymphocytes and Thymocytes

The majority of CD4⁺CD8⁻, CD4⁻CD8⁺, and $\gamma\delta^+$ thymic emigrants and peripheral blood lymphocytes (85–98%) expressed CD44 (Fig. 2) and this did not

change over the three ages examined (data not shown). CD44 appeared to be up-regulated on $\gamma\delta^+$ T cells prior to export because the majority of $\gamma\delta^+$ thymocytes expressed much lower levels of CD44 than $\gamma\delta^+$ emigrants or peripheral blood lymphocytes (Fig. 3). Whereas the majority of $\gamma\delta^+$ emigrants and peripheral blood lymphocytes expressed similar levels of CD44, there was an appreciable number of CD44^{lo} $\gamma\delta^+$ cells in the mature blood T-cell population (Fig. 3). It was also apparent that many $\gamma\delta$ emigrants and peripheral blood lymphocytes expressed considerably lower levels of CD44 than did the corresponding CD4⁺CD8⁻ populations (Fig. 2).

The majority of CD4⁺CD8⁻, CD4⁻CD8⁺, and $\gamma\delta^+$ thymic emigrants and peripheral blood lymphocytes (80–100%) expressed CD58 (Fig. 2), and as with CD44 expression, this did not change over the three ages examined (data not shown). Most $\gamma\delta^+$ thymocytes expressed much higher levels of CD58

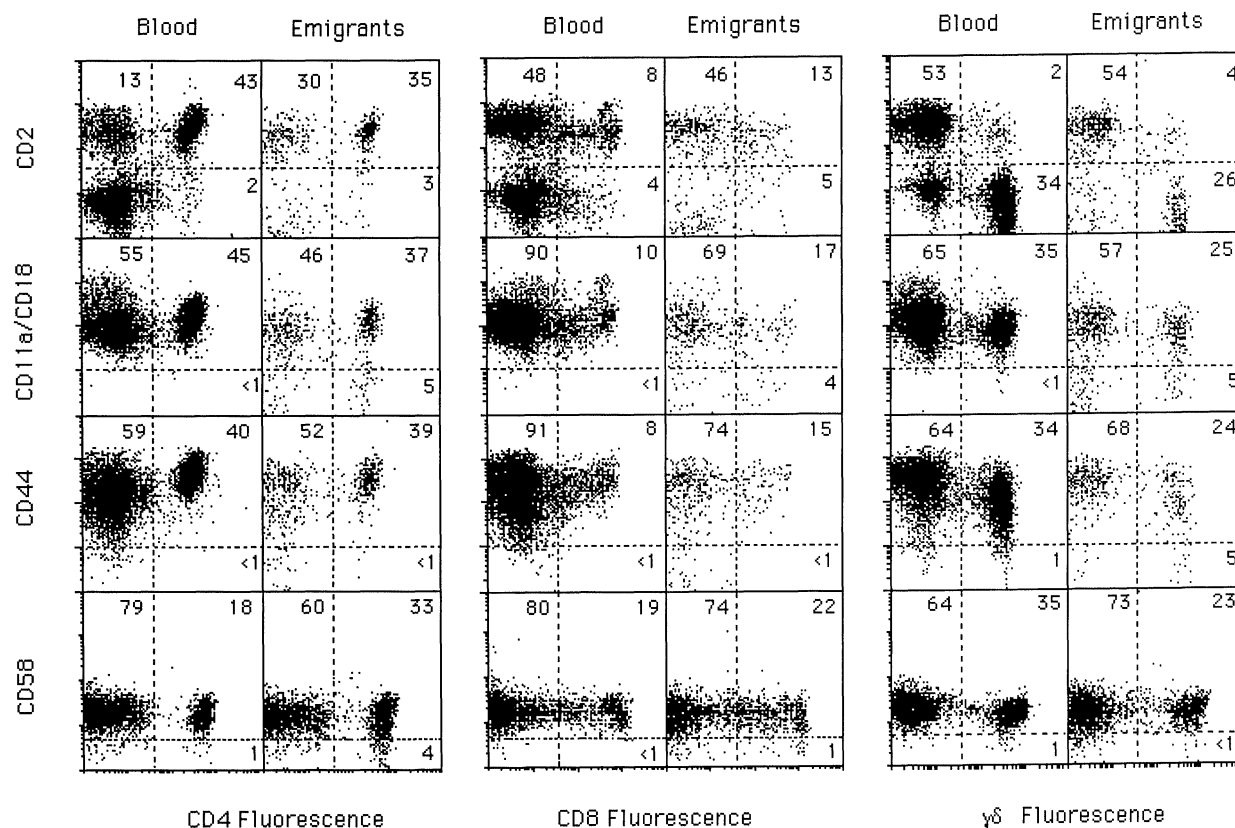

FIGURE 2. Two-color FACS plots of CD2, CD11a/CD18, CD44, and CD58 expression versus CD4, CD8, and $\gamma\delta$ expression on mature peripheral blood lymphocytes and thymic emigrants from 3-month-old lambs. Emigrants were identified by *in situ* FITC labeling, and the surface phenotypes for both mature T cells and thymic emigrants were determined by two-color immunofluorescence staining using phycoerythrin (adhesion molecules) and Texas Red (T-cell subset). Quadrant markers were set based on isotype-matched control mAbs.

than $\gamma\delta^+$ thymic emigrants and mature T cells suggesting that CD58 was down-regulated on $\gamma\delta^+$ T cells prior to their export from the thymus (Fig. 3). The expression of CD58 on $\alpha\beta$ T cells in the thymus was not examined but $CD4^+CD8^-$ and $CD4^-CD8^+$ emigrants and mature T cells expressed the same low levels of CD58 as the corresponding $\gamma\delta$ T-cell populations (Fig. 2).

DISCUSSION

There have been many studies on the up-regulation of adhesion molecules by $\alpha\beta$ T cells upon activation and, together with CD45 isoform expression, changes in these molecules have been combined in an attempt to define the naive and memory status of T cells (Mackay et al., 1990; Picker and Butcher, 1992; Mackay, 1993a, 1993b; Picker et al., 1993a, 1993b). Very little is known about the expression of these molecules on $\gamma\delta$ T cells, either in terms of naive and memory status, or activation state. Here, it has been possible to examine postthymic maturational changes in the expression of several adhesion molecules on both $\alpha\beta$ and $\gamma\delta$ T cells as they progress into the mature T-cell pool, in the very different environments that prevail in the lamb before and after birth (summarized in Fig. 4).

CD2 is a lymphocyte surface molecule thought to be critically involved in the adhesion and activation of $\alpha\beta$ T cells during immune responses (Springer et al., 1987; Collins et al., 1994) and thymocyte expansion (Reinherz, 1985). Whereas the majority of both fetal and postnatal $\alpha\beta$ thymic emigrants expressed CD2, most $\gamma\delta$ emigrants in the experiments reported here were $CD2^-$. Although previous reports have described a lack of CD2 expression by $\gamma\delta$ T cells (Mackay et al., 1988a; Giegerich et al., 1989), the experiments reported here demonstrate a substantial population of $CD2^+$ $\gamma\delta$ T-cell emigrants, which declined from 44% in 120-day-old fetuses to 17% after birth. Thus, there was a significant decrease in the export of $\gamma\delta^+CD2^+$ cells with gestational age. In the previous reports, a monoclonal antibody to T19, a cell-surface protein expressed exclusively on a subset of $\gamma\delta$ T cells in ruminants (Mackay et al., 1989), was used to identify $\gamma\delta$ T cells, but because $\gamma\delta$ T cells comprise both $\gamma\delta^+T19^+$ and $\gamma\delta^+T19^-$ cells, the $\gamma\delta^+CD2^+$ cells may have been contained within the $T19^-$ subset and therefore missed in these earlier reports.

CD2 is also believed to play a crucial role as a coreceptor involved in inside-out signaling resulting in increased adhesion between the T lymphocyte and the antigen-bearing cell in both antigen-specific and antigen-independent lymphocyte activation (Collins et al., 1994). If CD2 functions as a coreceptor on $\gamma\delta$ T cells in a similar fashion to $\alpha\beta$ T cells, the presence of a large population of $CD2^-$ $\gamma\delta$ thymic emigrants raises the possibility that $CD2^-$ $\gamma\delta^+$ T cells may represent an immature lineage of $\gamma\delta$ T cells

FIGURE 3. Level of expression of CD11a/CD18, CD44, and CD58 on $\gamma\delta^+$ thymocytes, thymic emigrants (shaded), and peripheral blood lymphocytes in 3-month-old lambs. Emigrants were identified by *in situ* FITC labeling, and the surface phenotypes were determined by two-color immunofluorescence staining using phycoerythrin (adhesion molecules) and Texas Red ($\gamma\delta^+$ cells). Dash lines represent the point beyond which staining was considered positive relative to isotype-matched control mAbs.

MATURATION PATHWAY FROM A DEVELOPING THYMOCYTE TO A MATURE T CELL

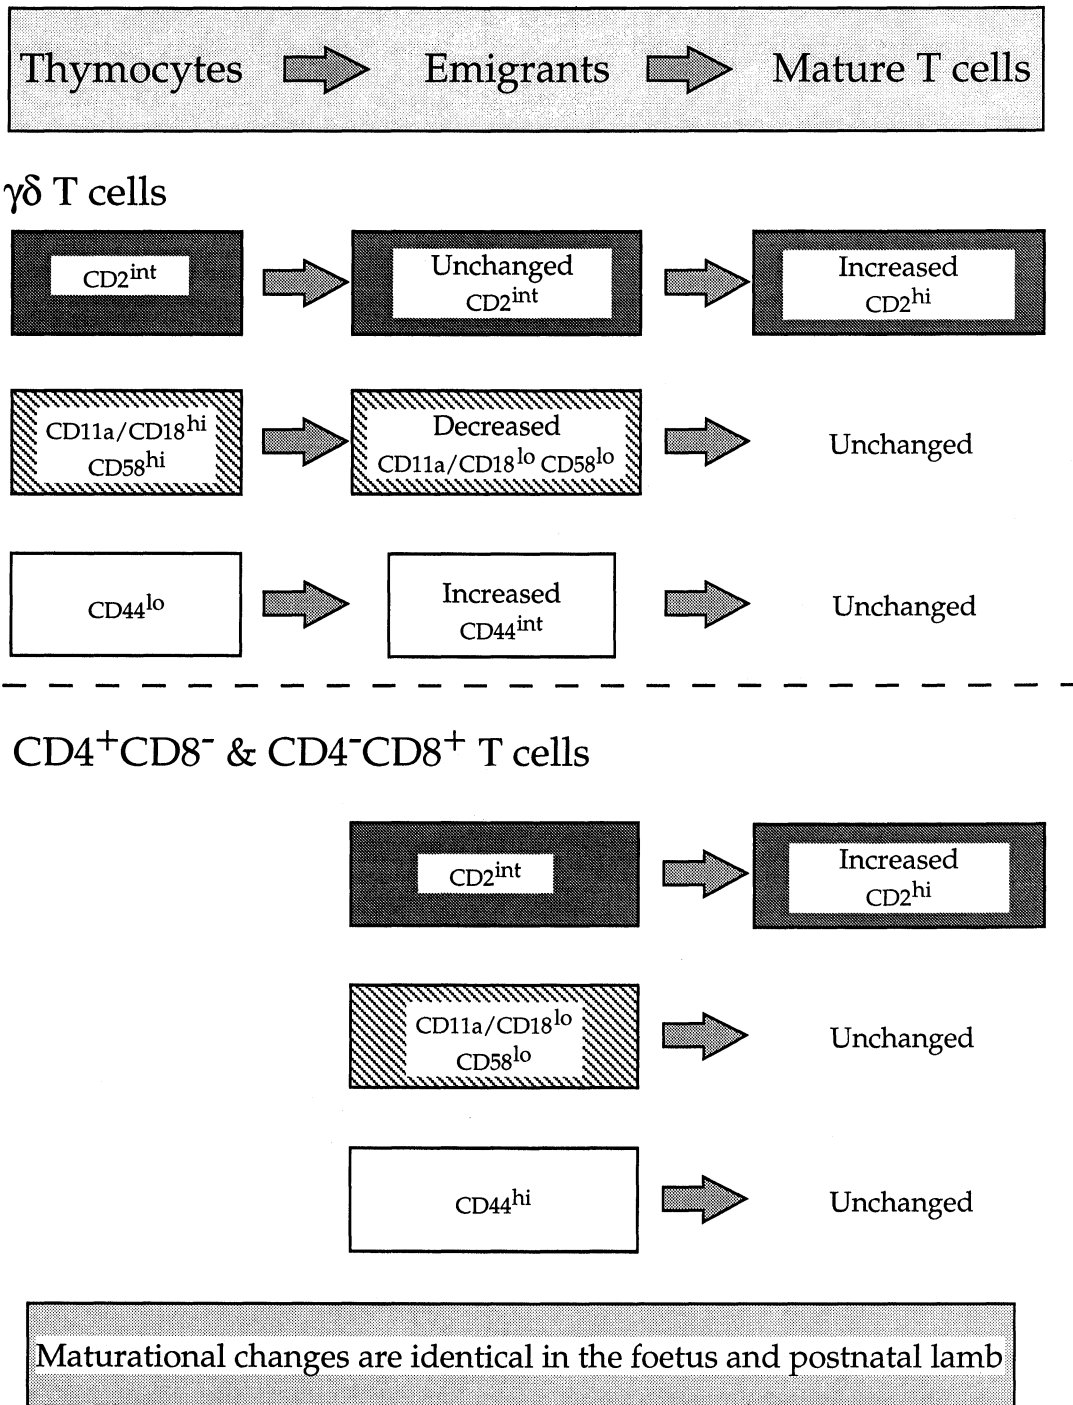

FIGURE 4. Scheme showing antigen-independent maturation of adhesion-molecule expression on γδ and αβ T cells in the fetus and postnatal lamb.

that would seem unlikely considering up to 73% of $\gamma\delta$ T cells in the thymus express CD2 and the overwhelming majority of peripheral $\gamma\delta$ T cells are CD2⁻. It is also possible that CD2⁻ and CD2⁺ $\gamma\delta$ T cells may represent separate lineages, as has been suggested in rats, where $\gamma\delta$ T cells in lymph nodes are CD2⁺, whereas those in intestinal epithelium are CD2⁻ (Kühnlein et al., 1994). Alternatively, activation of $\gamma\delta$ T cells may occur in a different manner from $\alpha\beta$ T cells.

As there appeared to be developmentally regulated changes in the export of CD2⁺ $\gamma\delta$ T cells, we examined the level of expression of CD2 on thymic emigrants and peripheral blood lymphocytes of the fetus and lamb. In the antigen-free environment of the fetus, both thymic emigrants and mature T cells are naive cells and should therefore express the same low level of CD2. In contrast, thymic emigrants in the lamb are naive, but their mature T-cell counterparts consist of both naive and memory T cells. As such, differences in the level of expression of CD2 might be expected between thymic emigrants and peripheral blood lymphocytes in the lamb, but not in the fetus. When compared with mature peripheral blood T cells, $\gamma\delta$ emigrants and thymocytes were found to express lower levels of CD2. This increase in CD2 expression on mature cells occurred in both fetal and postnatal lambs. Thus, the postthymic maturational changes in the expression of CD2 that occurred in the $\gamma\delta$ T-cell population appeared to be developmentally regulated rather than due to any antigen-induced changes.

Although CD4⁺CD8⁻ and CD4⁻CD8⁺ thymocytes were not examined here, the same increased expression of CD2 was found between CD4⁺CD8⁻ and CD4⁻CD8⁺ emigrants and mature T cells, as was found for $\gamma\delta$ T cells. In sheep, it has been reported that CD4 and CD8 single-positive medullary thymocytes, as well as a large fraction of CD4⁺CD8⁻ thymocytes, express a relatively high level of CD2, whereas the "double-negative" cells in the thymus contain mostly CD2⁻, some CD2^{lo}, and a few CD2^{hi} cells (Mackay et al., 1988a; Giegerich et al., 1989). This suggests that there may be down-regulation of CD2 on $\alpha\beta$ T cells upon emigration from the thymus followed by up-regulation as these cells progress into the mature peripheral T-cell pool.

CD58 is thought to mediate intercellular adhesion of CD58⁺ cells with thymocytes, natural killer cells, and mature $\alpha\beta$ T lymphocytes in its role as the

ligand for CD2, and its expression is up-regulated on memory cells (Springer, 1990). Along with other Ig superfamily members, CD58 can also act as a costimulatory molecule for IL-2 production and the proliferation of CD4⁺ T cells (Hogg and Landis, 1993). An analysis of the expression of CD58 on thymic emigrants revealed that, unlike CD2, the vast majority of both $\gamma\delta$ and $\alpha\beta$ emigrants expressed CD58, albeit at a low level. In contrast, virtually all thymocytes expressed higher levels of CD58, suggesting that down-regulation of CD58 may be a final maturational stage of both $\gamma\delta$ and $\alpha\beta$ thymocytes prior to emigrating from the thymus.

CD11a/CD18 or LFA-1 is a member of the integrin family of cell-surface heterodimers that participate in a range of cell-to-cell and cell-to-extracellular matrix interactions in the immune system (Hynes, 1992). In the experiments reported here, we have shown that $\gamma\delta$ thymocytes, in the fetus close to term and in the postnatal lamb, expressed a higher level of CD11a/CD18 than both $\gamma\delta$ emigrants and mature T cells. Recent studies have reported that CD11a/CD18 and ICAM-1 interactions within the thymus are involved in T-cell differentiation and negative selection (Fine and Kruisbeek, 1991; Carlow et al., 1992, #1453). In this context, the down-regulation of CD11a/CD18 on $\gamma\delta$ thymocytes may indicate a final stage in T-cell development prior to their export to the periphery.

LFA-1/ICAM-1 adhesion pathways are important in many cell-to-cell interactions in the immune system and a range of cell types such as thymocytes, peripheral blood lymphocytes, monocytes, and neutrophils have been shown to express differential levels of CD11a and CD18 (Tamatani et al., 1991a). Although we have shown there is no difference in the level of CD11a/CD18 expression on thymic emigrants and mature peripheral blood T cells, recent studies have shown that activation of lymphocytes induces qualitative changes in the avidity and ligand specificity of LFA-1 (Tamatani et al., 1991b). For example, qualitative but not quantitative changes in the expression of LFA-1 on lymphocytes result in the binding of activated, but not resting lymphocytes, to high endothelial venules in lymph nodes (Tamatani et al., 1991b).

Very little difference was apparent in the expression of CD11a/CD18 between the mature T-cell subsets with one exception. At 140 days gestation and 3 months of age, a small population of CD4⁻CD8⁺ lymphocytes expressed a high level of CD11a/CD18. This CD11a/CD18^{hi} population

represented a greater proportion in the 3-month-old lamb than in the fetus at term. As this population was not present in the young fetus, but was present in the fetus at 140 days gestation, it cannot be due to antigen-induced activation of the CD4⁻CD8⁺ cells, as the ovine fetus is devoid of extrinsic antigen.

CD44 is a polymorphic cell-surface protein that is expressed on a wide variety of cell types and is believed to be involved in a variety of biological reactions by recognizing multiple ligands (Haynes et al., 1989; Toyama-Sorimachi et al., 1993; Toyama-Sorimachi and Miyasaka, 1994). In humans, CD44 is expressed at uniformly low levels on naive T cells (Picker et al., 1990), whereas memory T cells in both mice and humans have been shown to express higher levels of CD44 than their naive counterparts (Budd et al., 1987; Sanders et al., 1988). In the experiments reported here, fetal and postnatal $\alpha\beta$ and $\gamma\delta$ emigrants expressed CD44 at the same level as mature T cells, suggesting that CD44 expression is not easily related to naive or memory status. Kelly and Scollay (1990) have shown that a proportion of thymic emigrants and mature T cells in both 5-day-old and adult mice express CD44, indicating that CD44 is also expressed on virgin T cells in mice. In our experiments, a population of CD44^{lo} $\gamma\delta$ T-cell emigrants that emerged in fetal life was also present in lambs in the mature T-cell population, suggesting developmental rather than antigenic regulation. In contrast, the experiments of Kelly and Scollay (1990) indicated a clear increase in CD44 expression from thymic emigrants to mature T cells, so that either different isoforms of CD44 were being detected in these studies or there is a major difference in the expression of CD44 between the two species.

An interesting observation was that emigrants expressed higher levels of CD44 than the majority of thymocytes, suggesting up-regulation of CD44 before emigration. In addition, there was a small population of thymocytes that expressed the same high levels of CD44 as thymic emigrants, possibly representing mature thymocytes that are about to emigrate. This supports there being selective export of CD44^{hi} cells from the ovine thymus, as has been suggested for the human and inferred for the sheep, by the high-level expression of CD44 on human and ovine medullary thymocytes (de los Toyos et al., 1989), a situation quite different from that in the mouse.

Nothing is known of the factors that regulate cell exit from the thymus or of any role for adhesion

molecules in the exit mechanism(s). The vast majority of $\gamma\delta$ T cells express the adhesion molecules CD11a/CD18, CD44, and CD58, but only a proportion express the adhesion molecule CD2, both as thymic emigrants and mature T cells. Whereas it is unclear whether the down-regulation of CD11a/CD18 and CD58 on $\gamma\delta$ T cells is necessary before $\gamma\delta$ T cells can leave the thymus, it is clear that the expression of CD2 is not mandatory for $\gamma\delta$ T-cell export. Upon emigration from the thymus, both $\gamma\delta$ and $\alpha\beta$ T cells express mature levels of CD44, CD11a/CD18, and CD58, but there is postthymic maturation of CD2 expression. The changes in adhesion-molecule expression on thymic emigrants reported here, and the changes in L-selectin and CD45RA expression on thymic emigrants (Witherden et al., 1984a, 1994b) previously reported apparently do not rely on the presence of antigen, but would seem to occur as part of the normal development of a T cell.

MATERIALS AND METHODS

Animals

Fetal lambs of known gestational age were obtained from timed matings of virgin merino ewes with merino rams, 120 and 140 days prior to the experiments. Three-month-old postnatal lambs were obtained from the same breeding program.

Intrathymic Injection of FITC

For injection of FITC into the fetal thymus, the uterus was exteriorized and the fetus exposed according to the procedure described previously (Smeaton, et al., 1969). The head and neck of the fetus were then delivered through an incision in the uterus. From this point, the procedures for exposing the thymus and the intrathymic injection of FITC were essentially the same for both fetal and postnatal animals. A midline incision was made in the neck of the fetus or the lamb and the cervical thymus exposed after blunt dissection of the overlying tissue. A small biopsy of thymus was taken for phenotypic analysis. An aqueous solution of FITC, at 500 $\mu\text{g}/\text{ml}$, was then heated to 37°C and injected at multiple sites directly into the thymus, essentially according to the technique described previously for the adult murine thymus (Weissman, 1967; Scollay et al., 1980). Blood was taken 1 h following intrathymic injection for phenotypic analysis. Blood samples

were taken from the jugular vein, carotid artery, or by cardiac puncture, and heparin was added to a final concentration of 100 U/ml (Commonwealth Serum Laboratories, Parkville, Victoria, Australia). Red cells were lysed using NH_4Cl red cell lysis buffer (Mackay et al., 1988b).

Monoclonal Antibodies

Monoclonal antibodies (mAb) directed against the lymphocyte cell-surface antigens; CD4 (44-38/44-97), CD8 (38-65), the $\gamma\delta$ TCR (86D), CD2 (36F), CD11a/CD18 (F10-150), CD44 (25-32), and CD58 (L180-1) were obtained as undiluted tissue-culture supernatant or as ascites fluid from Dr. M. Brandon (University of Melbourne, Victoria, Australia) and Dr. C. Mackay (Basel Institute for Immunology, Basel, Switzerland) and have been described previously (Hünig, 1985; Maddox et al., 1985; Mackay et al., 1988a; 1988c; 1989; 1990; 1992). For two colour immunofluorescence staining, the mAb to CD4, CD8, and the $\gamma\delta$ TCR were used as purified proteins conjugated to biotin (Goding, 1986).

Thymocyte Suspensions

The cervical thymus was removed and placed into HBSS (ICN-Biomedicals, Seven Hills, NSW, Australia) containing 2% lamb serum (Gibco Laboratories, NY) (HBSS-2%LS) at 4°C. Suspensions were made by teasing the organs through a wire mesh into HBSS-2%LS. The cells were washed three times by centrifugation (10 min, 300 g, swing-out rotor, 4°C) and resuspended in HBSS-2%LS.

Immunofluorescence Staining and Flow Cytometry

All reagents were pretitrated and used at optimum concentrations to give maximal positive staining with minimal background. Before immunofluorescence staining and between reaction steps, cells were washed three times in HBSS-2%LS. All incubations were for 30 min and cells were kept on ice or at 4°C at all times. 10^7 lymphocytes were first incubated with 50 μl mAb, followed by 50 μl phycoerythrin (PE) conjugated anti-mouse Ig F(ab')₂ (Silenus Laboratories, Hawthorn, Victoria, Australia). In order to saturate free-binding sites on the anti-mouse Ig, cells were incubated with a 10-fold excess of mouse Ig (w/w compared to the anti-mouse Ig; Chemicon International Inc., CA). Cells

were then incubated with 50 μl biotinylated mAb followed by 50 μl of a streptavidin-conjugated tandem of PE and Texas red (Tandem, Southern Biotechnology, Birmingham, AL). Cells were fixed in 100 μl (10^8 cells/ml) of 3% paraformaldehyde and kept in the dark at 4°C for no longer than a week before FACS analysis. Flow cytometric analysis was performed using a FACScan (Becton Dickinson, Sunnyvale, CA). Thymocytes and peripheral blood lymphocytes were identified by forward angle and 90° light scatter. Phenotypic analysis of FITC⁺ cells (thymic emigrants) was performed by triggering on FITC rather than on forward scatter and electronic gating on forward angle and 90° light scatter, allowing more efficient data collection. Nonspecific staining was determined by an isotype-matched control mAb. Comparisons of fluorescence intensity were only made between samples that were stained and analyzed at the same time, and care was taken to ensure they contained similar numbers of positive cells. Except for thymic emigrants (FITC⁺ cells), where as many cells as possible were analyzed (approximately 1000), 10,000 cells were analyzed for each sample.

Statistical Analysis

The percentage of each subset was compared between age groups and between lymphocyte sources using a one-way analysis of variance. Those showing variation were then compared using an unpaired Student's *t*-test (Glantz, 1987). A value of $p \leq 0.05$ was considered significant.

ACKNOWLEDGMENTS

We would like to thank Ms. J.E. Holder and Dr. E.A. Washington for their help in preparing this manuscript. This work was supported by the National Health and Medical Research Council of Australia.

Special Issue on Molecular Genetic Markers in Female Reproductive Cancers

Call for Papers

Cancer is a complex genetic disease as a result of accumulated genomic alterations which serve as the driving force in initiating tumor development and propelling tumor progression. The Darwinian evolution theory of cancer predicts that clinically detectable tumors harbor the molecular genetic changes that are causally related to uncontrolled growth, survival in dynamic microenvironment, invasion into surrounding normal tissues, and metastasis to distant organs. Various forms of genomic abnormalities have occurred in cancers, such as point mutations, DNA copy number alterations, and chromosomal rearrangements. Proto-oncogenes are typically activated by gene amplifications, gene translocations, and activating intragenic mutations, whereas tumor suppressors are inactivated by gene deletions (loss of heterozygosity or homologous deletion), inactivating intragenic mutations, and epigenetic silencing. Recent advances in molecular genomic technology and the success of human genome project have empowered investigators with new tools in analyzing cancer genome in great details and have expedited the discovery of new cancer-associated genes. Decoding the genetic history present in tumor DNA, as well as identification and characterization of molecular changes involving cancer-associated genes and the pathways they controlled, has not only shed new light on the molecular etiology of cancer, but also has promised for the development of new diagnostic markers and novel therapeutics.

In this special issue, we invite authors to present original research articles as well as timely reviews that will stimulate the continuing efforts in identifying and characterizing new biomarkers and therapeutic targets in female reproductive cancers including breast, ovarian, endometrial, and cervical cancer. Studies that evaluate mutations, bioinformatics for genome-wide data analysis, biomarkers to predict prognosis and treatment outcome, as well as preclinical and clinical studies in new therapeutic development are particularly welcome. Translational studies that focus on assessing the clinical significance of expression of biomarkers are also encouraged.

Before submission authors should carefully read over the journal's Author Guidelines, which are located at <http://www>

[.hindawi.com/journals/jo/guidelines.html](http://www.hindawi.com/journals/jo/guidelines.html). Prospective authors should submit an electronic copy of their complete manuscript through the journal Manuscript Tracking System at <http://mts.hindawi.com/> according to the following timetable:

Manuscript Due	June 1, 2009
First Round of Reviews	September 1, 2009
Publication Date	December 1, 2009

Special Issue on Wet Laboratory Tools Widely Used in Plant Genomics

Call for Papers

There are numerous laboratory tools developed and available for use in plant genomics; however, they are usually published in books or in journal separate issues, making them accessed and updated inconveniently. Collection/integration of the wet laboratory tools that are widely used, further improved and advanced in a special issue that is open-accessed, is crucial to and greatly helpful for research of plant genomics and other disciplines of plant biology. The tools below listed themes are called for this special issue, but other tools that are useful for plant genomics are always welcome. The reviewed articles in other systems (e.g., mammalian system) that are potentially applicable to plant genomics are also considered for publication in the special issue. The emphasis and themes are as follows:

- Cytogenetics Tools
 - Fish, fiber-fish, and gish
 - Chromosome banding methods (i.e., C-banding, N-banding) and karyotyping
 - Microscopic analysis
- Molecular Tools
 - Isolation of conventional and megabase-sized DNA and RNA isolation (including sRNAs)
 - Construction of genomic DNA libraries (small-insert and shotgun libraries, large-insert BAC and BIBAC libraries) and cDNA libraries
 - Screening large-insert libraries and targeting specific chromosome regions' tools (i.e., pools for PCR, filters)
 - DNA sequencing (plasmid and BAC end sequencing, high-throughput 454 sequencing)
 - Genetic and physical mapping, QTL analysis, and DNA markers
 - Gene expression analyses (i.e., microarray analysis, qRT-PCR, SAGE, RAGE)
 - Mutagenesis (physical and chemical mutagenesis, T-DNA tagging, transposable element)
 - Virus-induced gene silencing and RNAi silencing and yeast two-hybrid system
 - Methods for genetically modified organism analysis
 - PCR methods (tail PCR, emulsion PCR, RACE-PCR, multiplex PCR, etc.)
- Analytical and Biochemical Tools
 - SDS-PAGE and PAGE and two-dimensional gel electrophoresis
 - Heterologous gene expression, production, and purification of recombinant proteins
 - Immunoblotting and immunohistochemistry of proteins and DNA molecules

Authors should follow the International Journal of Plant Genomics manuscript format described at the journal site <http://www.hindawi.com/journals/ijpg/>. Prospective authors should submit an electronic copy of their complete manuscript through the journal Manuscript Tracking System at <http://mts.hindawi.com/>, according to the following timetable:

Manuscript Due	March 1, 2009

Special Issue on Epithelial Ovarian Cancer: Focus on Targeted Therapy

Call for Papers

The treatment of ovarian cancer has evolved to include more options for targeted therapy as the biology of the disease becomes better elucidated. Many different targets have been studied in a wide variety of tumor types. In addition, there are surgical issues that remain controversial in epithelial ovarian cancer. Moreover, the role of dose density in ovarian cancer also remains unresolved. We invite authors to present original research articles as well as review articles that will continue to stimulate the continuing evolution of the treatment of epithelial ovarian cancer.

The main topics of interest are as follows:

- Timing of surgery, upfront versus interval debulking
- Aggressiveness of surgical intervention at initial surgery, pro and con papers
- Dose dense therapy
- Failure of triplet therapy used as first line therapy
- Treatment options at first relapse, platinum sensitive disease versus resistant
- Timing of treatment of recurrent disease, either at time documentation of relapse or at time of symptomatic progression pro versus con
- Targeted therapies
 - Anti-VEGF
 - BRCA positivity and PARP inhibitors
 - EGFR and other TKIs
 - PI3Kinase and Akt/mTOR pathway inhibitors

Before submission, authors should carefully read over the journal's Author Guidelines, which are located at <http://www.hindawi.com/journals/jo/guidelines.html>. Prospective authors should submit an electronic copy of their complete manuscript through the journal Manuscript Tracking System at <http://mts.hindawi.com/>, according to the following timetable:
