Degradation mechanisms and development of silicon carbide refractories

Ron Etzion

A thesis submitted in partial fulfilment of the requirements
for the degree of Doctor of Philosophy at the
University of Auckland, 2008

Abstract

The lifetime of aluminium reduction cells is of considerable importance in the operating economics of an aluminium smelter. Not only are the cell materials costly, but cell life is also key in minimizing production downtime and the waste material generated in the cutting-out and relining of a reduction cell. This lifetime is increasingly driven by two components of the cell lining: the carbon cathode and the sidewall refractories which are the primary containment of the metal and electrolyte.

Silicon nitride bonded silicon carbide (SNBSC) refractories are the current state-of-the-art sidewall materials. These materials are formed by encapsulation of SiC particles in a silicon nitride matrix, by nitridation of silicon at high temperatures under a nitrogen atmosphere. In this study the mechanisms of the corrosion of silicon nitride bonded silicon carbide refractories in an aluminium reduction cell environment were examined.

Microstructural analysis of SNBSC materials by: X-ray diffraction, solid state NMR, Raman spectroscopy, XPS, and SEM, identified variations in α/β Si₃N₄ ratio and porosity in the binder phase, with higher porosity levels and β Si₃N₄ content found in the interior part of the brick. Unreacted metallic silicon was observed only as a crystalline phase inside SiC grains and is not associated with the binder phase.

SNBSC samples from eight different commercial refractory manufacturers were tested in an industrial aluminium cell environment, both by immersion in industrial cells and in the laboratory. The samples showed extensive attack and considerable differentiation between the samples. The effects on the corrosion rate of porosity levels, amount of binder, α/β Si₃N₄ ratio, free Si content in the binder, and different factors in the environment were examined in the laboratory scale trials. A laboratory scale testing rig with some novel features, such as a rotating anode, was developed to examine corrosion resistance of samples under electrolysis conditions in molten cryolite at up to 1000 °C.

Corrosion test results, supported by thermodynamic calculations, identified the Si₃N₄ binder as the reactive phase in SNBSC materials, especially in the gas phase above the bath level. High porosity levels and high β Si₃N₄ fraction in the binder showed a statistically significant contribution to the corrosion rate in lab-scale corrosion trials. Commercial materials are also

highly inhomogeneous in the distribution of the β Si_3N_4 phase as mentioned above, which complicates sample selection and the interpretation of corrosion test results.

The crystal morphology of β Si_3N_4 is suggested as the reason for the high reactivity of these materials. This morphology characterised by elongated rod-like shape crystals with hexagonal cross section, presents a higher surface area compared to α Si_3N_4 crystals containing mainly flat plate crystals. In the light of this observation, the binder phase in selected samples was deliberately modified to convert a significant fraction of the α Si_3N_4 to β Si_3N_4 . Corrosion rates measured from these modified samples in general support the argument that the crystallographic form of silicon nitride contributes to corrosion rate.

The proposed corrosion mechanism for SNBSC materials in the aluminium reduction cell atmosphere is based on combination of oxidation of the binder followed by attack of corrosive gases to produce volatile SiF_4 . Thus the binder phase is initially passivated below the electrolyte level on the sidewall, where exposure to corrosive gases is limited, but occurs more rapidly in the area above the electrolyte/air interface. The intrusion of electrolyte into the refractory and capillary transport up the sidewall is a key in accelerating this reaction.

Acknowledgments

Completing this thesis was quite a challenge, and I would not have been able to complete it without the help and support of a few people that gave their time and thoughts to keep this research going in the right direction.

My supervisor Prof. Jim Metson deserve special thanks for his help, the good advice that he provided me, and the good discussions that we had that helped me to go through the research and writing of this thesis, and mostly for his patience listening to all the problems and difficulties along the way.

I would like to thank David Cotton who helped installing the equipment in the lab, gave his thoughts to improve and create new features into the experimental rig. He also made sure the operations are safe and check that I'm safe when I came to the lab late at night.

I would also like to thank Tania Groutso who helped me a lot with the XRD analysis of so many samples and coming up with the correct method to do this analysis. Dr. Jimmy Bester who contributed his writing experience correcting my writing. Many thanks to Nick Depree who contributed his computer modelling skill to produce the heat flow model, and Pascal Lavoie who taught me how to harness statistic analysis to verify the results.

I would also like to express my gratitude to Catherine Hobbis, Colin Doyle, Bryony James and Michel Neiuwoudt who helped with microstructure analysis.

Thanks to Andrew Frellek from Bell-Bay smelter for helping to organise and execute the industrial-scale experiment. Thanks to Luoyang Institute of Refractory Research for initiating and financing much of the project.

Thanks to my Family – my parents who didn't have the chance to be with me till the end of this research, my sister for good advice. Special thanks to Aum for her love, patience and encouragement when work got hard and I had to keep working till the odd hours.

Figure 6-36: Corrosion rate as a function of SiC content for un-soaked samples with SiC content > 80%.....	144
Figure 6-37: Corrosion rate as a function of SiC content for pre-soaked samples (SiC < 83%).	144
Figure 6-38: Corrosion rate as a function of SiC content for pre-soaked samples (SiC > 83%).	145
Figure 6-39: Cross section taken from brick B, and the location of the segments that were analysed.	147
Figure 6-40: β Si ₃ N ₄ content in the binder measured on segments that were cut along two cross sections taken from brick B. The numbered locations are shown in Figure 6-39.....	147
Figure 6-41: Corrosion rate as a function of β Si ₃ N ₄ content of the bonding phase in samples that were pre-soaked in bath prior to corrosion test.....	148
Figure 6-42: Corrosion rate as a function of β Si ₃ N ₄ content of the bonding phase in samples that were not soaked in bath prior to corrosion test.	149
Figure 6-43: Corrosion as a function of β Si ₃ N ₄ content for the un-soaked sample with a thickness below 16mm.	150
Figure 6-44: Corrosion as a function of β Si ₃ N ₄ content of un-soaked sample with a thickness above 16mm.	150
Figure 6-45: Un-soaked narrow samples after corrosion test. In the back of the picture, the two samples, having a depth of 30mm compared to the other samples with a depth of 15mm.	151
Figure 6-46: Corrosion rate as a function of β Si ₃ N ₄ content of un-soaked samples. High correlation was found between the corrosion rate and β Si ₃ N ₄ content with calculated $R^2 = 0.82$	151
Figure 6-47: Intergrowth of molten silicon between the phases. The Si metal is clearly in intimate contact with the SiC phase, indicative of inter growth of the Si around the SiC grains [33].	153
Figure 6-48: XPS Si 2p analysis of sample H, internal zone (left) and external zone (right). The free Si peak at the BE= 99-100eV is absent. The dominant phase is SiC (BE=100.4 and 101.1), other phases are nitride (BE= 102eV) and Oxide (BE= 103eV).....	154

Figure 6-49: XRD analysis of core part of brick H confirming the presence of free Si, and among the Si_3N_4 phases only the β Si_3N_4 is present. () Si (7.0%), (✦) $\text{Si}_2\text{N}_2\text{O}$ (7.9%), (●) β Si_3N_4 , (■) SiC.	155
Figure 6-50: Back scattered electron SEM image of un- exposed sample H (left) and corroded sample C (right) depict free Si in the core of the SiC grain (white spots) and not in the bonding matrix.	155
Figure 6-51: Solid state NMR of fresh sample B showing the presence of SiC (peaks at -14.41, -20.48, -25.0 ppm) Si_3N_4 (peak at -48.58ppm) and $\text{Si}_2\text{N}_2\text{O}$ (peak at -61.60ppm) with absence of free Si (peaks around -100ppm).	156
Figure 6-52: SNBSC samples (25x20x185mm) after corrosion test. Degradation of the samples is observed mainly in the bath-gas interface and in gas phase.	158
Figure 6-53: SNBSC sample after soaking treatment for 48 hours. No damage observed on the samples except colour change.	159
Figure 6-54: Comparison between corrosion rates of samples exposed to bath and to electrolytic conditions.	159
Figure 6-55: SEM image of Si_3N_4 bonding phase of the fresh sample, characterizes with short grain crystals.	164
Figure 6-56: SEM image of Si_3N_4 bonding phase of fresh sample, long needle-like crystals prominent in the pores.	165
Figure 6-57: SEM image of cross section of SNBSC sample after heat treatment. A long grain crystals of Si_3N_4 are prevailing the bonding phase.	165
Figure 6-58: A higher magnification(x3500) SEM image of the Si_3N_4 bonding phase of SNBSC sample after heat treatment.	166
Figure 6-59: Samples in graphite basket before electrolysis.	166
Figure 6-60: Cumulative corrosion rate of samples D in three repetitive experiments. Samples D1 and D2 are fresh samples and D3and D4 were altered by nitridation.	167
Figure 6-61: Cumulative corrosion rate of nitrided and normal SNBSC samples: α - samples with high α - Si_3N_4 content, β -samples with high β - Si_3N_4 content. See Table 6-8 for experiments results.	168
Figure 7-1: Isothermal contours in conventional reduction cell with passive cooling [83].	176
Figure 7-2: The reactivity of Si_3N_4 and SiC with CO_2 in the temperature range of 350-1000°C.	178
Figure 7-3: The reactivity of Si_3N_4 and SiC with CO in the temperature range of 350-1000°C.	178
Figure 7-4: The reactivity of Si_3N_4 and SiC with oxygen according to reactions 7-5 and 7-6... ..	179

Figure 7-5: The reactivity of Si_3N_4 and SiC with HF in the temperature range of 350-1000°C.	179
Figure 7-6: The reactivity of Si_3N_4 and SiC with NaAlF_4 and CO_2 in the temperature range of 350-1000°C.	180
Figure 7-7: Reactivity of Si_3N_4 towards different gases present in the reduction cell atmosphere at the temperature range of 350-1000°C.....	181
Figure 7-8: Reactivity of SiO_2 with HF (red curve) and NaAlF_4 (blue curve) according to reactions 7-11 and 7-12. Spontaneous reaction could occur with HF in temperature below 850°C.	182
Figure 7-9: Reactivity of Si_3N_4 and SiO_2 in aqueous HF environment.....	183
Figure 7-10: The reactivity of Si_3N_4 and SiC with cryolite and CO_2 in the bath zone. The reactivity of Si_3N_4 is increasing with increasing temperature while the opposite trend occurs in the SiC phase.....	184
Figure 7-11: Schematic oxidation of Si_3N_4 in oxygen or air (left) the SiO_2 and $\text{Si}_2\text{N}_2\text{O}$ serving as diffusion barrier for oxygen. On the right, formation of sodium silicate layer with enhanced oxygen diffusion [84].	185
Figure 7-12: Oxidation of Si_3N_4 in dry air containing 0.98vol% NaNO_3 vapours. The oxidation rate was measured by thickness of the Si_3N_4 samples [84].	185
Figure 7-13: Weight gain due to oxidation of sodium carbonate coated Si_3N_4 in wet air at 1300°C. Equivalent sodium oxide weights are shown as mg per bar [85]......	186
Figure 7-14: Weight gain due to oxidation of Si_3N_4 in wet air. The Si_3N_4 sample was coated repeatedly with 5.9mg of sodium oxide [85].	187
Figure 7-15: Reactivity of silicon oxide and sodium silicate in wet gaseous HF atmosphere. In the upper temperature range the sodium silicate oxidation layer is more reactive than SiO_2	188
Figure 7-16: SEM image of bonding phase of SNBSC sample before heat treatment. Large pores filled with needle-like α Si_3N_4 crystals and short flat crystals were observed in the bonding phase.	189
Figure 7-17: SEM image of bonding phase of SNBSC sample after heat treatment with domination of elongated spike-shape β Si_3N_4 crystals.	190
Figure 7-18: Porosity levels as a function of β Si_3N_4 content in pre-soaked samples. No statistically significant correlation is observed.	193
Figure 7-19: Porosity as a function of β Si_3N_4 content in un-soaked samples. A very weak correlation was observed with $R^2=0.17$	193
Figure 7-20: Normal plot of the residuals.....	195

Figure 7-21: Surface plot of corrosion rate as a function of porosity and β Si_3N_4 content at 80.15% SiC content.	196
Figure 7-22: Surface plot of corrosion rate as a function of porosity and SiC content.....	197
Figure 7-23: Surface plot of corrosion rate as a function of SiC content and Si_3N_4 content.....	197
Figure 7-24: Optimization plot of the predicted corrosion rate as a function of increasing value of parameter in three different factors.	198

List of Tables

Table 1-1: Typical composition and approximate densities of refractory and insulating materials used in aluminium reduction cell [3].....	5
Table 1-2: Carbon lining materials for aluminium electrolysis pots [3].	14
Table 1-3: A qualitative comparison of sidewall materials [17].....	20
Table 1-4: Silicon carbide refractories, typical properties by bonding phase [17].	21
Table 1-5: Properties and composition of different bonding phase SiC bricks [2].....	21
Table 1-6: Mass change during oxidation test, test condition: heating rate 120°K/hour, air flow rate: 4m ³ /hour at 30Pa, sample size 8-15kg [8].	25
Table 1-7: Comparison HMOR of cryolite corroded SiC materials and unreacted SiC materials [19].	29
Table 3-1: Results of oxidation test of SNBSC materials in different oxidation environments [37].	46
Table 3-2: Possible reactions in the bath zone ΔG_{1200K} in kJ [41].....	53
Table 4-1: Main peaks with their 2 theta location, (CuK α X-rays) used in the calculation of phase quantity by Gazzara & Messier method	69
Table 4-2: Values of L (hkl) for peaks of α and β Si ₃ N ₄	69
Table 4-3: Diffraction files used for the silicon nitride /silicon carbide ratio, and silicon and silicon oxynitride quantification.	71
Table 4-4: α and β Si ₃ N ₄ content in samples from exterior and interior part of SNBSC brick cross sections.	72
Table 4-5: Parameters used in the ²⁹ Si NMR experiments for various pure compounds.....	75
Table 4-6: Data obtained from deconvolution: (A)- interior part of the sample H, (B)-exterior parts of the sample H,.....	81
Table 4-7: Raman shifts of different pure phases.	83
Table 4-8: Binding energies in the Si2p region of Si, SiC, Si ₃ N ₄ , and SiO ₂	86
Table 4-9: Atomic percent of elements in exterior and interior parts of block H.	89
Table 4-10: Peaks in the Si 2p region (after charging correction) of samples from the interior and exterior of block H.	90
Table 4-11: Quantification of the different silicon species, in samples taken from the exterior, and interior of SNBSC brick H.	90
Table 4-12: EDX analysis of points 1-4 in Figure 4-27observed within the silicon carbide grain in SNBSC material.	96
Table 5-1: Water density in temperature range of 15-25°C.	108

Table 5-2: A spreadsheet with the name, the marking of the samples, and the calculation of their density, volume, and porosity.	109
Table 6-1: Initial porosity and corrosion rate of samples after industrial-scale corrosion test...	123
Table 6-2: α and β Si_3N_4 content of samples A-H from exterior and interior parts of the bricks [61].	124
Table 6-3: Width of the different bricks tested in the corrosion test.....	127
Table 6-4: α and β Si_3N_4 content in samples from the exterior and interior parts of the SNBSC brick cross section.	146
Table 6-5: Corrosion rate of samples exposed to gas phase for 36 and 96 hours, and 48 hours after bath soaking for 48 hours.....	160
Table 6-6: Parameters of nitridation experiments, and properties of the nitrided samples.	163
Table 6-7: Porosity and β Si_3N_4 fraction in the binder changes in SNBSC samples after the nitridation process.	163
Table 6-8: Cumulative corrosion rate of nitrided and normal SNBSC samples. Samples D corrosion test was repeated three times and samples B mid 5-6 and B core was repeated twice.	169
Table 7-1: The factors that contributed to the corrosion rates according to the statistical model, and their estimated regression coefficients with p-values for each factor.....	194
