Keywords:	Pig, Drug absorption, Magnetic resonance imaging, Stomach fluid
Abstract:	Although the study of bioequivalence waivers in humans is already well-established, their application and translation into animals, which are complicated by differences in physiology, have only recently become subjects of interest. The main purpose of this paper is to quantify the liquid volume affecting drug dissolution in pig stomachs. We used magnetic resonance imaging (MRI) to scan 18 Bama miniature pigs weighing 15, 30 or 50 kg. Amira 6.0.1 software was used for 3D image processing. We found that the gastric fluid volume had a linear relationship with the weight of pig ($R^2 = 0.9935$) over this weight range. The pig weight therefore could be used as a surrogate for the fasted gastric fluid volume. After combining data of gastric fluid secretion and drinking water volumes, our results could be used as a reference for the evaluation of oral drug absorption in pigs.

28 INTRODUCTION

29 *In vivo* bioequivalence waivers are currently available for many human drugs. The World Health
30 Organization (WHO), the US Food and Drug Administration (FDA), the European Medicines Agency (EMA)
31 and the China Food and Drug Administration (CFDA) have all published detailed biowaiver guidelines
32 (FDA, 2015; EMEA, 2010; WHO, 2006; CFDA, 2016). Bioequivalent waivers, which rely on the
33 biopharmaceutical classification system (BCS) framework to classify drugs, are selective waivers in which
34 *in vitro* studies are accepted in lieu of *in vivo* studies. The BCS is based on the water solubility and
35 intestinal permeability of the active pharmaceutical ingredient (API) in oral solid dosage forms. Further
36 BCS subclasses for *in vivo* predictive dissolution have been proposed in particular for BCS II and IV drugs
37 (Tsume, Mudie, Langguth, Amidon, & Amidon, 2014).

38 However, differences in physiology mean that existing bioequivalence studies in humans cannot be
39 directly extrapolated to animals (Martinez et al., 2004). As drug solubility is strongly influenced by pH,
40 solvent composition, volume, temperature and effective dosage (Martinez & Fahmy, 2012), differences in
41 first-pass metabolism and pH of the gastrointestinal tract may lead to differences in oral bioavailability
42 between humans and animals (Dressman, 1986). Current classifications of human oral drug solubility are
43 based on a volume of 250mL, which is the volume of a standard glass of water ingested upon oral drug
44 administration (FDA, 2015). However, pigs have a larger stomach volume than humans (Karali, 1995),
45 therefore it is necessary to factor in the *in vivo* gastric fluid volume when calculating oral drug absorption
46 in pigs.

47 Magnetic resonance imaging (MRI) has previously been used to study gastrointestinal absorption of
48 drugs in humans (Mudie et al, 2014). In that study, twelve healthy volunteers underwent an upper
49 abdomen scan before and after drinking 240 mL of water. The study showed that a fasted stomach
50 contained 35 ± 7 mL of resting water. Immediately after water drinking, the gastric fluid volume rose to

1
2
3 51 242 ± 9 mL (mean ± SEM). These data help to reveal the physiological relevance of *in vitro* testing
4
5
6 52 methods and computer-based drug transport analyses. However, this method has not been applied to
7
8 53 animals yet, to our knowledge.
9

10
11 54 The aim of this study is to use MRI to image the abdomens of miniature pigs with different weights,
12
13
14 55 and to establish the relationship between the volume of gastric fluid and the body weight of pigs, so as to
15
16 56 aid the prediction of the pharmaceutical performance of oral solid drugs in our future studies.

58 MATERIALS AND METHODS

59 Materials and equipment

60 Image scans were performed using a 1.5 T Siemens Symphony MRI scanner (Siemens Healthcare,
61 Munich, Germany). Sodium pentobarbital was purchased from the Sigma Chemical Co. (St. Louis, MO).
62 An anesthesia agent Sumianxin II was purchased from the Shengda Animal Pharmaceutical Co. (Jilin,
63 China).

64 Animals

65 This study was performed using three groups of Bama miniature pigs with six pigs in each group,
66 weighing 15, 30, or 50 kg, respectively. Pigs were purchased from the Shichuang Experimental Animal
67 Center (Beijing, China) and housed using a 12 h light–dark cycle. Pigs were fasted for 18 h and deprived of
68 water for 6 h prior to experiments. Sumianxin II (0.2 mL/kg) was injected intramuscularly at first, then
69 anesthesia was administered by intravenous injection of sodium pentobarbital (0.1 mL/kg) ten minutes
70 later. This procedure has a minimal effect on gastrointestinal secretion. This study was approved by the
71 Qingdao Agricultural University Animal Experiment Committee [license Number: SYXK (SD) 20170005]
72 and the animals were maintained in accordance with Qingdao Agricultural University guidelines for the
73 care and use of laboratory animals.

74 Experiments

75 Pigs were placed at a prone position with a two-channel circular polarized abdominal coil wrapped
76 around the abdomen (Figure 1). During the scan, at least one person was present to observe the state of
77 the pigs in case of an emergency. T2-weighted MRI sequences were used to image the abdominal organs.
78 The parameters used to scan the transverse and sagittal planes were a TR of 1100 ms, TE of 122 ms, slice
79 thickness of 4 mm, and FOV of 308×380 mm. The characteristic sequence used to scan the coronal plane
80 was a TR of 4.5 ms, and TE of 2.25 ms. The average scanning time per pig was about 15 min. After a scan

1
2
3 81 was completed, the pig was gently removed from the scanning room and allowed to wake up. All pigs had
4
5
6 82 stable anesthesia during the scan and reached a sober state within the prescribed time after completion
7
8 83 of the trial. No severe complications were observed, and good quality images were obtained from all pigs.
9
10
11 84 After fasting for 18 h, the stomachs were shrunken but liquid could still be identified as bright regions in
12
13 85 the images (Figure 2). The Amira 6.0.1 graphics software was used for 3D image processing. The MRI
14
15
16 86 images were manually segmented by two independent investigators skillful in using the software to
17
18 87 determine the amount of stomach fluid in each pig. Both investigators were blind to the protocol to
19
20
21 88 prevent biasing of the study results. After interactive segmentation the gastric fluid was volume rendered
22
23
24 89 and measured. The maximum and minimum differences between the two investigators were 12.5, and
25
26 90 3.2 mL. The final volume was an average of the two calculations.
27
28

RESULTS

Continuous cross-sectional scanning images were used for 3D image processing. Measured gastric fluid volumes are given in Table 1. The stomach fluid volumes of pigs in the 15, 30, and 50 kg groups in the fasting state were 32.51 ± 4.19 mL, 78.87 ± 6.26 mL, and 162.20 ± 8.39 mL, respectively, with a p-value < 0.0001 suggesting the results are statistically significant (Figure 3). The gastric fluid volume has a linear relationship with the pig weight using the following equation:

$$y=3.7304x-26.931 \quad (1)$$

where x is the gastric fluid volume and y is the pig weight ($R^2=0.9935$).

1
2
3 104 **DISCUSSION**
4

5
6 105 As the first major organ in which the drug is absorbed in the body, the amount of liquid in the
7
8 106 stomach plays an important role in drug absorption. The gastric fluid volume is important for
9
10
11 107 bioequivalence studies of swine drugs. As far as we know, there is still no gold standard to determine the
12
13 108 volume of gastric fluid in pigs. Therefore, our results represent one of the first *in vivo* quantitative
14
15
16 109 measures of the gastric fluid volume of pigs.
17

18
19 110 Concerning MRI imaging, one procedural difference between pigs and humans is that pigs must
20
21 111 undergo anesthesia to prevent vomiting and other reactions during the scanning process. Anesthesia was
22
23
24 112 also performed to prevent inhalation of food, gastric fluid, and other substances into the trachea due to
25
26 113 dyspnea or respiratory failure. This causes difficulties in drinking water administration in pigs before MRI
27
28
29 114 scans.
30

31
32 115 It is noteworthy that the amount of porcine gastric fluid during fasting could be on the conservative
33
34 116 side. Pigs undergoing a diet or other external stimuli may have an increased gastric secretion and a higher
35
36
37 117 gastric fluid volume. Hence, the equation (1) provides a relatively conservative estimation. Concerning
38
39 118 whether the equation (1) can be extrapolated beyond the 15-50kg range, it is highly likely that when pigs
40
41
42 119 reach higher body weights, the relationship between the body size and gastric fluid volume becomes
43
44
45 120 curvilinear and not linear. This is due to the fact that different tissues do not increase proportionally
46
47 121 with maturity, and the increase in weight in adult pigs is associated with body fat.
48
49

50 122 For pigs, the main form of oral drug administration is soluble powder. Therefore, the effective
51
52 123 amount of liquid in pig stomachs is dependent on gastric fluid volume and water intake. Previous studies
53
54
55 124 show that when pigs are in a neutral environment, where free water and standard dry feed are available,
56
57
58 125 they consume about 2100 - 2700 mL drinking water per kg feed (Li et al., 2005; Shaw et al., 2006). Gastric
59
60 126 emptying is another problem that cannot be ignored when calculating the effective fluid volume. These

1
2
3 127 factors need to be considered together with the fasted gastric fluid volume. Beyond its utility in
4
5
6 128 determining oral drug dissolution according to the BCS, the relationship between gastric fluid volume and
7
8 129 weight can be applied to other studies, such as the absorption of nutrients in the diet.
9

10
11 130 In future studies we will analyze the amount of gastric fluid produced and drinking water consumed
12
13 131 over the course of a day to more accurately quantify the gastric fluid volume.

3 133 **CONCLUSION**
4

5
6 134 Our results show that, during fasting, the gastric fluid volume in pigs is linearly related to the body
7
8 135 weight. This result can be used for the calculation of oral drugs solubility in pigs.
