## Abstract

In this note, we prove that every countably compact space with quasi- $S_1$ -diagonal is compact. However, it is shown that it need not be metrizable.

1991 Math. Subject Classification: 54E30, 54E35.

Key words and phrases: compact; countably compact; quasi- $S_1$ ;  $\aleph_1$ -compact.

## 1 Introduction

In this work we are interested in properties  $\mathcal{P}$  which satisfy the implication **countably compact** +  $\mathcal{P} \rightarrow$  **compact**, that is, properties  $\mathcal{P}$  such that every countably compact space with property  $\mathcal{P}$  is compact. For very useful survey of this problem, see [9].

H. Shiraki [8] has proven that a countably compact space with a quasi- $G_\delta$ -diagonal is compact metrizable. Here, we prove that the implication above is true for  $\mathcal{P} =$  quasi- $S_1$ -diagonal. By an example we show that the implication above does not get metrizability when  $\mathcal{P} =$  quasi- $S_1$ -diagonal.

A space  $X$  has a **quasi- $G_\delta$ -diagonal** (resp. **quasi- $S_1$ -diagonal**) if there exists a countable family  $\mathcal{G} = \{\mathcal{G}_n\}_{n \in \mathbb{N}}$  of collections of open subsets (resp. of collections of subsets

for which  $st(x, \mathcal{G}_n)$  is open for each  $x \in X, n \in \mathbb{N}$ ) such that for any distinct  $x, y \in X$ , there exists  $n \in \mathbb{N}$  such that  $x \in st(x, \mathcal{G}_n) \subset X - \{y\}$ . A space  $X$  is **closed-complete** if every ultrafilter of closed sets in  $X$  with the countable intersection property has nonempty intersection. A space  $X$  is  **$\aleph_1$ -compact** if every uncountable subset of  $X$  has a limit point in  $X$ . A space  $X$  is **real compact** if it is a closed subspace of a product of copies of the real line.

## 2 Main Results

**Theorem 2.1** *An  $\aleph_1$ -compact space with quasi- $S_1$ -diagonal is closed-complete.*

*Proof.* Let  $X$  be  $\aleph_1$ -compact having a quasi- $S_1$ -sequence  $\{\mathcal{G}_n\}_{n \in \mathbb{N}}$ , and let  $\mathcal{F}$  be an ultrafilter of closed sets in  $X$  with the countable intersection property. For each  $n \in \mathbb{N}$ , let  $A_n = \{x \in X : x \in \bigcup \mathcal{G}_n \text{ and } X - st(x, \mathcal{G}_n) \in \mathcal{F}\}$ . We begin by showing that  $X \neq \bigcup_{n \in \mathbb{N}} A_n$ . Suppose instead that  $X = \bigcup_{n \in \mathbb{N}} A_n$ . Then there exists  $m \in \mathbb{N}$  such that  $A_m$  meets  $\bigcap \mathcal{K}$  for every countable subset  $\mathcal{K}$  of  $\mathcal{F}$ , and since  $A_m \subset \bigcup \mathcal{G}_m$ , there exists  $F \in \mathcal{F}$  such that  $F \subset \bigcup \mathcal{G}_m$ . By Zorn's Lemma, there is a subset  $D$  of  $A_m \cap F$  such that

- (1) if  $x, y \in D$  with  $x \neq y$ , then  $x \notin st(y, \mathcal{G}_m)$
- (2)  $A_m \cap F \subset \bigcup_{x \in D} st(x, \mathcal{G}_m)$ .

If  $D$  is uncountable, then  $D$  has a limit point  $p \in X$ . Then  $p \in F \subset \bigcup \mathcal{G}_m$ , so  $p \in G$  for some  $G \in \mathcal{G}_m$ . Then  $st(p, \mathcal{G}_m)$  is an open neighbourhood of  $p$  and contains infinitely many points of  $D$ . Let  $x \in D$  one of them,  $G' \in \mathcal{G}_m, p, x \in G'$ . Now  $st(x, \mathcal{G}_m)$  is an open neighbourhood of  $p$ , hence it contains a point  $y \in D$  distinct from  $x$ . Let  $x, y \in G'' \in \mathcal{G}_m$ ; this is contrary to (1). Hence  $D$  is countable, so  $A_m \cap F \cap (\bigcap_{x \in D} (X - st(x, \mathcal{G}_m))) \neq \emptyset$ , which contradicts (2). It follows that  $X \neq \bigcup_{n \in \mathbb{N}} A_n$ , so there exists  $x \in X$  such that  $x \notin A_n$  for every  $n \in \mathbb{N}$ . Let  $M = \{n \in \mathbb{N} : x \in \bigcup \mathcal{G}_n\}$ . Then for every  $n \in M$  we have  $X - st(x, \mathcal{G}_n) \notin \mathcal{F}$ , so there exists  $F_n \in \mathcal{F}$  with  $F_n \subset st(x, \mathcal{G}_n)$ . Therefore

$$\emptyset \neq \bigcap_{n \in M} F_n \subset \bigcap_{n \in M} st(x, \mathcal{G}_n) = \{x\},$$

and hence  $\{x\} = \bigcap_{n \in M} F_n \in \mathcal{F}$ . But then  $x \in \bigcap \mathcal{F}$ , and we conclude that  $X$  is closed-complete. ■

**Corollary 2.2** *A countably compact space with a quasi- $S_1$ -diagonal is compact.*

*Proof.* Every countably compact space is  $\aleph_1$ -compact, and every countably compact closed-complete space is compact (see [1, Theorem 3.6] or [4, Theorem 2.2]). ■

Almost real-compact spaces are discussed in [2], [4] and [7].

**Corollary 2.3** *An  $\aleph_1$ -compact, countably paracompact (resp. Tychonoff countably compact) space with a quasi- $S_1$ -diagonal is almost real-compact (resp. real-compact).*

*Proof.* Every closed-complete, countably paracompact (resp. Tychonoff countably compact) is almost realcompact [4, Theorem 2.1] (resp. real-compact [2, Theorem 1.10]). ■

**Corollary 2.4** *An  $\aleph_1$ -compact, normal countably paracompact space with a quasi- $S_1$ -diagonal is real-compact.*

*Proof.* Every normal countably paracompact space is countably compact [6, Corollary 2]. ■

**Example 2.5** [5] *The Alexandroff double  $A(I)$  of the closed unit interval  $I = [0, 1]$  is a non-separable compact space with quasi- $S_1$ -diagonal. (Refer to [3] for more about the Alexandroff double and the notations.)  $A(I)$  has quasi- $S_1$ -diagonal.*

*Proof.* For each  $x \in I$  and  $A \subset I$ , let  $x^1$  and  $A^1$  be the duplicates of  $x$  and  $A$  respectively. Let  $B_n(x) = (x - \frac{1}{n}, x + \frac{1}{n}) \cap I$  and  $S_n(x) = \{\{x, y\} : y \in B_n(x)\} \cup \{\{x, y^1\} : y \in B_n(x) - \{x\}\} \cup \{(B_n(x))^1\}$  for each  $x \in I$  and each  $n \in \mathbb{N}$ . Let  $\mathcal{G}_0 = \{\{x^1\} : x \in I\}$  and  $\mathcal{G}_n = \bigcup\{S_n(x) : x \in I\}$  for each  $n \in \mathbb{N}$ . Then, the sequence  $\langle \mathcal{G}_n : n \in \mathbb{N} \cup \{0\} \rangle$  is a quasi- $S_1$ -sequence. The following properties of  $\langle \mathcal{G}_n : n \in \mathbb{N} \cup \{0\} \rangle$  justify our claim.

1.  $\bigcup\{\bigcup \mathcal{G}_n : n \in \mathbb{N} \cup \{0\}\} = A(I)$ ;
2. for each  $x \in I$ ,  $st(x, \mathcal{G}_0) = \emptyset$  and  $st(x^1, \mathcal{G}_0) = \{x^1\}$ ;

3. for each  $x \in I$  and  $n \in \mathbb{N}$ ,  $st(x, \mathcal{G}_n) = \{B_n(x) \cup (B_n(x))^1\} - \{x^1\}$  and  $st(x^1, \mathcal{G}_n) = \{B_n(x) \cup (B_n(x))^1\} - \{x\}$  while  $x^1 \notin \overline{st(x, \mathcal{G}_n)}$ ;
4. For each  $x \in I$ , we have  $\bigcap \{\overline{st(x, \mathcal{G}_n)} : n \in \mathbb{N}\} = \{x\}$  and  $\bigcap \{\overline{st(x^1, \mathcal{G}_n)} : n \in \mathbb{N} \cup \{0\}\} = \{x^1\}$ .

Thus , a compact space with quasi- $S_1$ -diagonal need not be metrizable. ■
