Abstract

In this paper we introduce the concepts of a quasi- G_δ^* -diagonal and quasi- $w\Delta$ -space as generalizations of the concepts of G_δ^* -diagonal and $w\Delta$ -space respectively. It is shown that a quasi-Moore space may be characterised in terms of these concepts. As a consequence we obtain the following metrization theorems: every paracompact $w\Delta$ -space with quasi- G_δ -diagonal is metrizable and every collectionwise normal σ quasi- $w\Delta$ -space is metrizable.

1991 Math. Subject Classification: 54E30, 54E35.

Key words and phrases: Moore space, quasi- G_δ^* -diagonal, quasi- $w\Delta$ -space, perfect space, weak θ -refinable space.

1 Introduction

The concept of G_δ -diagonal [6] has been generalized by several topologists to a concept called quasi- G_δ -diagonal [5].

A countable family $\{\mathcal{G}_n : n \in \mathbb{N}\}$ of open covers of a space X is called a **G_δ^* -diagonal**, if for each $x \in X$ we have $\bigcap_{n \in \mathbb{N}} \overline{st(x, \mathcal{G}_n)} = \{x\}$. A space X is said to be a **$w\Delta$ -space** if there exists a countable family $\{\mathcal{G}_n\}_{n \in \mathbb{N}}$ of collections of open subsets of X such that for each x in X , each sequence $\{x_n\}_{n \in \mathbb{N}}$ for which $x_n \in st(x, \mathcal{G}_n)$ for each $n \in \mathbb{N}$ has a cluster point. A space X is **weakly θ -refinable** if every open cover \mathcal{U} of X has an open refinement $\mathcal{V} = \bigcup_{n \in \mathbb{N}} \{\mathcal{V}_n\}$ such that, given $x \in X$, some \mathcal{V}_n has finite, positive order at x , which is

the cardinality of the collection $\{V \in \mathcal{V}_n : x \in V\}$. If, in addition, each \mathcal{V}_n is required to cover X , then we have the familiar concept of **θ -refinability**. A space with a σ -locally finite net is called a **σ -space**. A **quasi-Moore space (Moore space)** is a regular, quasi-developable space (developable space). Our main theorem characterises quasi-Moore space as those regular quasi- $w\Delta$ -spaces with quasi- G_δ^* -diagonal [see Definition 2.1]. From this we can characterise developable spaces as those perfect quasi- $w\Delta$ -spaces with quasi- G_δ^* -diagonal.

In section 2 we define a quasi- G_δ -diagonal and related properties. We then give connections between these properties; in particular we show that for perfect spaces the concepts of having a G_δ^* -diagonal and having a quasi- G_δ^* -diagonal are the same and quasi- $w\Delta$ -spaces are $w\Delta$ -spaces.

In section 3 we state and prove the main results, including our characterisation of quasi-Moore spaces as those regular quasi- $w\Delta$ -spaces with quasi- G_δ^* -diagonal, and our metrization theorems: every paracompact $w\Delta$ -space with quasi- G_δ -diagonal is metrizable and every collectionwise normal σ quasi- $w\Delta$ -space is metrizable.

We use the following notation: \mathbb{N} = the set of natural numbers; \overline{A} = the closure of a set A ; $st(x, \mathcal{G}) = \bigcup \{G : x \in G, G \in \mathcal{G}\}$, where \mathcal{G} is a collection of open subsets of a space; $\mathcal{G}^* = \bigcup \{G : G \in \mathcal{G}\}$; $ord(x, \mathcal{G})$ = the cardinality of the set of elements of \mathcal{G} containing x .

2 Quasi- G_δ -diagonal, Quasi- G_δ^* -diagonal and Quasi- $w\Delta$ -spaces

Let $\mathcal{G} = \{\mathcal{G}_n : n \in \mathbb{N}\}$ be a countable family of collections of open subsets of a space X . Consider the following conditions on \mathcal{G} :

- (a) For each $x \in X$, $\{st(x, \mathcal{G}_n) : n \in \mathbb{N}, x \in \mathcal{G}_n^*\}$ is a local base at x ;
- (b) Each \mathcal{G}_n is a covering of X ;
- (c) For any distinct $x, y \in X$, there exists $n \in \mathbb{N}$ such that

$$x \in st(x, \mathcal{G}_n) \subset X - \{y\};$$

(d) For any distinct $x, y \in X$, there exists $n \in \mathbb{N}$ such that

$$x \in st(x, \mathcal{G}_n) \subset X - \{y\} \text{ and } ord(x, \mathcal{G}_n) < \omega;$$

(e) For any distinct $x, y \in X$, there exists $n \in \mathbb{N}$ such that

$$x \in \overline{st(x, \mathcal{G}_n)} \subset X - \{y\};$$

(f) For any distinct $x, y \in X$, there exists $n \in \mathbb{N}$ such that

$$x \in \overline{st(x, \mathcal{G}_n)} \subset X - \{y\} \text{ and } ord(x, \mathcal{G}_n) < \omega.$$

Definition 2.1 *X has a quasi- G_δ^* -diagonal (θ -quasi- G_δ^* -diagonal) if there exists such a family \mathcal{G} satisfying (e) [(f)]. Recall that X has a quasi- G_δ -diagonal (θ -quasi- G_δ -diagonal) if there exists such a family \mathcal{G} satisfying (c) [(d)]; X is a quasi-developable space if there exists such a family \mathcal{G} satisfying (a); X is a developable space if there exists such a family \mathcal{G} satisfying (a) and (b).*

From the definition it is clear that if the space X has a quasi- G_δ^* -diagonal (θ -quasi- G_δ^* -diagonal) then X has a quasi- G_δ -diagonal (θ -quasi- G_δ -diagonal). Relationships between quasi- G_δ^* -diagonal, θ -quasi- G_δ^* -diagonal and G_δ^* -diagonal are given by the following theorems.

Theorem 2.2 *A perfect space X has a G_δ^* -diagonal if and only if it has a quasi- G_δ^* -diagonal.*

Proof. Every G_δ^* -diagonal is a quasi- G_δ^* -diagonal. Conversely suppose that X has a quasi- G_δ^* -diagonal. Then there is a countable family $\mathcal{G} = \{\mathcal{G}_n\}_{n \in \mathbb{N}}$ of collections of open subsets of X such that, for any distinct points $x, y \in X$, there exists $n \in \mathbb{N}$ such that

$$x \in \overline{st(x, \mathcal{G}_n)} \subset X - \{y\}.$$

For each $n \in \mathbb{N}$, the set \mathcal{G}_n^* is open and hence, since X is perfect, \mathcal{G}_n^* is an F_σ -set. Thus $\mathcal{G}_n^* = \bigcup_j F_{nj}$, where each F_{nj} is a closed subset of X , for each $j \in \mathbb{N}$. For each ordered pair (n, j) of natural numbers, let

$$\mathcal{U}_{nj} = \mathcal{G}_n \cup \{X - F_{nj}\}.$$

Then $\{\mathcal{U}_{nj} : n, j \in \mathbb{N}\}$ is a countable family of open covers of X . For each $x \in X$ there is $n \in \mathbb{N}$ for which $x \in \mathcal{G}_n^*$. Then there is $j \in \mathbb{N}$ such that $x \in F_{nj}$. Thus $st(x, \mathcal{U}_{nj}) = st(x, \mathcal{G}_n)$ and hence $\bigcap_{n,j} \overline{st(x, \mathcal{U}_{nj})} = \{x\}$ so that X has a G_δ^* -diagonal. \square

Theorem 2.3 *Every θ -refinable space with G_δ^* -diagonal has a θ - G_δ^* -diagonal.*

Proof. Let X be a θ -refinable space and $\{\mathcal{U}_n\}_{n \in \mathbb{N}}$ be a countable family of open covers of X exhibiting the G_δ^* -diagonal property for X . For each $n \in \mathbb{N}$, let $\{\mathcal{V}_{nk}\}_{n,k \in \mathbb{N}}$ be a θ -refinement of \mathcal{U}_n . Then $\{\mathcal{V}_{nk}\}_{n,k \in \mathbb{N}}$ is a θ - G_δ^* -diagonal of X . \square

Theorem 2.4 *Every hereditarily weak θ -refinable space with quasi- G_δ^* -diagonal has a θ -quasi- G_δ^* -diagonal.*

Remark 2.5 It is easy to check that part (e) in Definition 2.1 is equivalent to: for each $x \in X$, $\bigcap_{n \in c(x)} \overline{st(x, \mathcal{G}_n)} = \{x\}$, where $c(x) = \{n \in \mathbb{N} : x \in \mathcal{G}_n^*\}$.

The following theorem gives a relationship between having a quasi- G_δ -diagonal and having a quasi- G_δ^* -diagonal (moreover θ -quasi- G_δ^* -diagonal).

Theorem 2.6 *Every regular hereditarily weakly θ -refinable space with quasi- G_δ -diagonal has a quasi- G_δ^* -diagonal (moreover has a θ -quasi- G_δ^* -diagonal).*

Proof. Let X be a regular, hereditarily weakly θ -refinable space with a quasi- G_δ -diagonal. Then there is a countable family $\{\mathcal{G}_n : n \in \mathbb{N}\}$ of collections of open subsets of X such that for each distinct $x, y \in X$, there exists $n \in \mathbb{N}$ such that $x \in st(x, \mathcal{G}_n) \subset X - \{y\}$. For each $n \in \mathbb{N}$, \mathcal{G}_n is an open cover of \mathcal{G}_n^* , a subspace of X . By regularity there is an open cover \mathcal{U}_n of \mathcal{G}_n^* , such that $\overline{\mathcal{U}_n} = \{\overline{U} : U \in \mathcal{U}_n\}$ refines \mathcal{G}_n . Moreover, there exists an open refinement $\bigcup_j \mathcal{V}_{nj}$ of \mathcal{U}_n such that for each $x \in \mathcal{G}_n^*$, there exists a $j \in \mathbb{N}$ such that $ord(x, \mathcal{V}_{nj}) < \omega$. Clearly $\bigcup_n \bigcup_j \mathcal{V}_{nj}$ is a σ -refinement of $\bigcup_n \mathcal{U}_n$, that is, $(\bigcup_j \mathcal{V}_{nj})^* = \mathcal{U}_n^*$ and \mathcal{V}_{nj} is a refinement of \mathcal{U}_n . Since

$$\begin{aligned} \overline{st(x, \mathcal{V}_{nj})} &= \overline{\bigcup \{V : V \in \mathcal{V}_{nj}, x \in V\}} = \bigcup \{\overline{V} : V \in \mathcal{V}_{nj}, x \in V\} \\ &\subset st(x, \overline{\mathcal{U}_n}) \subset st(x, \mathcal{G}_n), \end{aligned}$$

it follows that $\{\mathcal{V}_{nj} : n, j \in \mathbb{N}\}$ is a quasi- G_δ^* -diagonal of X (moreover it is a θ -quasi- G_δ^* -diagonal of X). \square

Bennett and Lutzer have shown that a quasi-developable space is hereditarily weakly θ -refinable [3, Proposition 7]. From this and Theorem 2.2 we have:

Corollary 2.7 *Every regular quasi-developable space has a θ -quasi- G_δ^* -diagonal.*

Another interesting consequence of Theorem 2.6 is the following:

Corollary 2.8 *Every regular space which has a σ -point finite base, has a θ -quasi- G_δ^* -diagonal.*

Proof. Bennett and Lutzer showed that if a space has a σ -point finite base then it is quasi-developable [3, Corollary 10]. Our corollary follows immediately from this and Corollary 2.7.

□

Theorem 2.9 *A perfect manifold has a quasi- G_δ^* -diagonal if and only if it is a Moore manifold.*

Proof. Immediate from [6, Theorem 2.15] and Theorem 2.6. □

Definition 2.10 *Let X be a space and $\mathcal{G} = \{\mathcal{G}_n : n \in \mathbb{N}\}$ a countable family of collections of open subsets of a space X . Then $\mathcal{G} = \{\mathcal{G}_n : n \in \mathbb{N}\}$ is called a quasi- $w\Delta$ -sequence for X if and only if :*

- (1) *for all x , $c(x) = c_{\mathcal{G}_n}(x) = \{n \in \mathbb{N} : x \in \mathcal{G}_n^*\}$ is infinite.*
- (2) *if $\{x_n\}_{n \in \mathbb{N}}$ is a sequence with $x_n \in st(x, \mathcal{G}_n)$ for all $n \in c(x)$ then $\{x_n\}_{n \in \mathbb{N}}$ has a cluster point.*

If the space X has a such countable family then it said to be a quasi- $w\Delta$ -space.

It is clear that if X is a $w\Delta$ -space then it is a quasi- $w\Delta$ -space and every quasi-developable space is a quasi- $w\Delta$ -space.

We now state and prove a relationship between quasi- $w\Delta$ -spaces and $w\Delta$ -spaces.

Theorem 2.11 *Every perfect quasi- $w\Delta$ -space is a $w\Delta$ -space.*

Proof. Let X be a perfect space and let $\mathcal{G} = \{\mathcal{G}_n : n \in \mathbb{N}\}$ be a countable family of collections of open subsets of a space X exhibiting the quasi- $w\Delta$ -property for X . Then $\mathcal{G}_n^* = \bigcup_{j \in \mathbb{N}} F_{nj}$, where each F_{nj} is a closed subset of X . Let the countable family of open covers $\{\mathcal{U}_{nj}\}_{nj \in \mathbb{N}}$ be defined as in the proof of Theorem 2.2, so that $st(x, \mathcal{U}_{nj}) = st(x, \mathcal{G}_n)$. Suppose that $\{x_{nj}\}_{nj \in \mathbb{N}}$ is a sequence such that $x_{nj} \in st(x, \mathcal{U}_{nj})$ for each $n, j \in \mathbb{N}$. For each $n \in c(x)$ choose j_n such that $x \in F_{nj_n}$. Let $y_n = x_{nj_n} \in st(x, \mathcal{U}_{nj_n}) = st(x, \mathcal{G}_n)$. Then we have $y_n \in st(x, \mathcal{G}_n)$, for each $n \in c(x)$, so $\{y_n\}_{n \in c(x)}$ has a cluster point. Since $\{y_n\}_{n \in c(x)} \subset \{x_{nj}\}_{nj \in \mathbb{N}}$ it follows that the sequence $\{x_{nj}\}_{nj \in \mathbb{N}}$ has a cluster point. \square

3 The main results

Hodel's theorem states that a space is developable if and only if it is a $w\Delta$ -space with a G_δ^* -diagonal [4]. We now extend Hodel's theorem.

Theorem 3.1 *A space is a quasi-Moore space if and only if it is a regular quasi- $w\Delta$ -space with quasi- G_δ^* -diagonal.*

Proof. Since the proof of the 'only if' part is evident, we prove the 'if' part. Let X be a space, $\{\mathcal{U}_n\}_{n \in \mathbb{N}}$ be a quasi- $w\Delta$ -sequence for X , and $\{\mathcal{V}_n\}_{n \in \mathbb{N}}$ be a quasi- G_δ^* -diagonal sequence for X .

For each $n \in \mathbb{N}$, let $\mathcal{G}_n = \{G : G = U \cap V, \text{ for some } U \in \mathcal{U}_n, V \in \mathcal{V}_m, m \geq n\}$. Then $\mathcal{G}_n^* \subseteq \mathcal{U}_n^*$ for all $n \in \mathbb{N}$. Suppose that $\{\mathcal{G}_n\}_{n \in \mathbb{N}}$ is not a quasi-development for X . Then there is a point $x \in \mathcal{G}_n^*$, a neighborhood M of x and a sequence $\{x_n\}_{n \in \mathbb{N}}$ such that, for all $n \in c(x)$, $x_n \in st(x, \mathcal{G}_n) - M$. Since $\{\mathcal{U}_n\}_{n \in \mathbb{N}}$ is a quasi- $w\Delta$ -sequence, it follows that $\{x_n : n \in c_u(x)\}$ has a cluster point p . Now $p \notin M$, since otherwise $x_n \in M$ for all but finitely many $n \in c_u(x)$. Thus $p \neq x$. Choose n large enough such that $p \notin \overline{st(x, \mathcal{V}_n)}$; there is no loss of generality if we assume that $st(x, \mathcal{V}_m) \subset st(x, \mathcal{V}_n)$, for all $m \geq n$. This implies that $\bigcup_{m \geq n} st(x, \mathcal{G}_m) \subset \overline{st(x, \mathcal{G}_n)}$. For every $k \geq n$, we have $x_k \in st(x, \mathcal{G}_k)$ so $x_k \in \bigcup_{m \geq n} st(x, \mathcal{G}_m) \subset \overline{st(x, \mathcal{G}_n)}$, and $x_k \notin V = X - \overline{st(x, \mathcal{G}_n)}$ for all $k \geq n$. Now we have $p \in V$ and V open, which contradicts the fact that p is a cluster point of $\{x_n\}_{n \in \mathbb{N}}$. Thus $\{\mathcal{G}_n\}_{n \in \mathbb{N}}$ is a quasi-development for X . \square

Corollary 3.2 *A space is a developable if and only if it is a perfect, quasi- $w\Delta$ -space with a quasi- G_δ^* -diagonal.*

The following theorem weakens the conditions of result 3.5 of [2]. By using Theorems 2.2 and 2.11 we obtain :

Theorem 3.3 *A regular hereditarily weakly θ -refinable space with quasi- G_δ -diagonal is a quasi-Moore space if it is a quasi- $w\Delta$ -space.*

Corollary 3.4 *Every paracompact $w\Delta$ -space with quasi- G_δ -diagonal is metrizable.*

From [2, Corollary 3.2] and Theorems 2.2 and 2.11 we have the following result:

Corollary 3.5 *A regular hereditarily θ -refinable $w\Delta$ -space with quasi- G_δ -diagonal is a Moore space.*

Theorem 3.6 *Every collectionwise normal σ quasi- $w\Delta$ -space is metrizable.*

Proof. Siwiec-Nagata [7], proved that a collectionwise normal σ $w\Delta$ -space is metrizable. Since σ -spaces are perfect, the result follows using Theorem 2.11. \square

Example 3.7

- (1) Let M be the Michael line [5], the *LOTS* M^* constructed from the generalized ordered (*GO*) space M has a quasi- G_δ -diagonal, but does not have a G_δ -diagonal, therefore has no G_δ^* -diagonal. From remark [5] and Theorem 2.2 M^* has a quasi- G_δ^* -diagonal.
- (2) Since the space X in example 2.6 [1] is quasi-developable, θ -refinable, regular, but not developable, it follows that X is a quasi- $w\Delta$ -space and from [2, Corollary 3.2], it is not a $w\Delta$ -space.

The relationship between some of the classes of spaces considered in this paper can be summarized in a diagram as follows.
