ENZYME IMMOBILIZATION ON WOOLEN CLOTH

Jingdong An

A thesis submitted in partial fulfillment of the requirements for the degree of Doctor of Philosophy in Engineering

Department of Chemical and Materials Engineering

The University of Auckland, New Zealand

May, 2010

Abstract

The objective of this research was to determine the feasibility and the limitation of using woollen cloth as a support matrix for enzyme immobilization. Lipase from pseudomonas fluorescens was selected as the model enzyme. Covalent binding protocol (CVB) with a polyethyleneimine (PEI) spacer and glutaraldehyde (GA) cross-linker was used as benchmark protocol.

It was found that lipases could be effectively immobilized onto woollen cloth by the benchmark CVB protocol. The immobilized activity was independent of the GA concentration and soaking time in the GA solution, but dependent on the GA solution pH (optimal at pH 9). The treatment time in lipase solution was found to be the rate-determining step in the immobilization: the immobilized activity increased steadily within 5 to 10 hours of soaking in lipase solution, after that, the increase plateaued to a maximum of 4 μmol pNPP.min-1. (g cloth)$^{-1}$.

The immobilized lipase was reasonably stable: when the immobilized cloth was stored in 0.05 M Tris buffer (pH 8.5) for more than 80 days in a refrigerator, more than 80% of the lipase activity remained. The optimum pH for both free and immobilized lipase is approximately the same, which may indicate that microenvironment for the free and immobilised lipase was not considerably different. The Michaelis Menten parameters for the free and immobilized lipase were determined: K_M and v_{max} for the free and immobilized lipase were 2.40, 3.16 mM and 153.76, 5.16 μmol pNPP.min^{-1} (mg lipase)$^{-1}$ respectively. The lipase-immobilized cloth exhibited excellent oily stain removal ability: after being stained with olive oil and stored for one day in air at room temperature, the oily stain could be easily removed by 0.05 M pH 8.5 Tris buffer without any detergent addition. This enhanced cleaning was stable also, after cloth was stored in air for almost one month, similar cleaning performance was still observed.

Despite the successfulness in the benchmark CVB method, it was found to be a challenge to further improve the immobilised activity by variation of the CVB protocol and using different cross-linkers, although the ESEM images and measurement of protein load showed there was potential to do so. This was probably due to the fact that there are a number of reactive groups on wool surface which are not very reactive with the cross-linker used, thereby reducing the extent of surface activation, resulting in limited immobilized activity.

To further reduce the lipase deactivation during immobilization, immobilization of the lipase via assistance of another enzyme was tried in order to eliminate the use of GA. Thus, lipase was

entrapped inside a casein gel formed on woollen cloth in the presence of Transglutaminase (mTGase). Lipases were successfully immobilized by this protocol. Unavoidable lipase leakage and high mass transfer resistance from the casein gel however made this protocol not very promising compared to the CVB benchmark protocol.

The benchmark CVB immobilization protocol was also applied to galactosidase. The overall performance of the immobilized galactosidase was poor compared to the lipase however. This may indicate that the CVB immobilization method used is not immediately transferable to other enzymes and that modifications are required to do so. Further investigation is therefore needed.

Overall, the results from this project have shown that it is feasible to immobilize enzymes onto woollen cloth, although surface treatment of the wool to produce more binding groups would improve the surface coverage.

ACKNOWLEDGEMENTS

I offer my sincere thanks to the following people and company. Without their helps, this project would not have been possible.

To Dr Darrell Alec Patterson, my thesis supervisor, for his many fruitful discussions, informative advice and encourage to me, constructive direction in analysis the data during my PhD study, especially in the last two and half years.

To Dr MD Monwar Hossain, my thesis supervisor, for his significant contribution on setting up the framework of this project and continuous support during my PhD study

To Prof Xiao Dong Cheng, my thesis supervisor, for his initiating of my PhD project and inspiration during my study

To Dr Emma Emanuelsson-Patterson, my thesis supervisor, for her trust, encourage and great support, especially in the last stage of my PhD research.

Thanks for the financial support for this project from the Bright Future Enterprise Scholarship (ENT 1552) provided by AgResearch Limited and Tertiary Education Commission (New Zealand). Also the helps from AgResearch Ltd are gratefully appreciated.

Thanks to all other stuff in the Chemical and Materials engineering department for providing a friendly environment and help during my study

Finally, I dedicate this thesis to my wife, who give me great encourage, consistent patience, and provide tremendous support to the family. This thesis is especially dedicated to my son, Songyang An.

Figure 4-9 ESEM image of the immobilized lipase on woollen cloth by the CVB protocol (1000 × magnification), the immobilization condition adopted was as follows: temperature 25 °C, cloth was first treated in pH 9.0 phosphate buffer for 10 min, followed by soaking in 1 mg. ml^{-1} lipase solution prepared in 0.1 M pH 8 phosphate buffer for 1 day. The agglomerations of immobilized chemicals, which are suspected to contain the lipase attached to the fibres,

can be observed on the wool fibre. It can also been seen that distribution of this aggregate is not even across the fibre surface. Instead, they concentrate on certain area of the fibre surface. In addition, the fibres in deep layer of the cloth seem have no aggregate coverage. 92
Figure 4-10 A further magnified ESEM picture of the immobilized lipase on woollen cloth by CVB method (5000 × magnification) , the immobilization condition adopted is as follows: temperature 25 °C, cloth was first treated in pH 9.0 phosphate buffer for 10 min, followed by soaking in 1 mg ml^{-1} lipase solution prepared in 0.1 M pH 8 phosphate buffer for 1 day. The appearance of aggregate can be seen more clearly in this image. 93
Figure 4-11 Magnified view of ESEM picture of the immobilized lipase on woollen cloth by CVB method (2500 × magnification), the immobilization condition adopted is as follows: temperature 25 °C, cloth was first treated in pH 9.0 phosphate buffer for 10 min, followed by soaking in 1 mg ml^{-1} lipase solution prepared in 0.1 M pH 8 phosphate buffer for 1 day. The coating on fibre surface can be clearly seen, which is most likely from PEI cross-linking. Less agglomeration material is present in this area.....94

Figure 6-5 ESEM image of lipase-immobilized area on woollen cloth prepared by the CRL protocol. The original magnifications from view A to view F are 500×, 2000×, 8000×, 16000 ×, 40000× and 80000 × respectively. Immobilization condition: Chlorinated woollen cloth, which was stored in 2% PEI solution at pH 8, was soaked in 2 mg ml^{-1} lipase solution pH 8.0 for 1 day, then cross-linked in 0.1% of GA solution prepared in 0.1 M phosphate buffer at pH 6.0 for 5 min. The images were taken after consecutive activity assay and all loss-associated lipases were washed off. View A is a general view of cloth fibre. In view B, a stingy structure can be observed on one of the cloth fibre. This structure is further enlarged in the view of C, D E, and F. In the high magnification image of view E and F, it can be found that the stringy structure is further composed of some fine grainy components, which most likely could be the sign of immobilized lipases. 125
Figure 6-6 ESEM image of immobilized lipase concentrated in defect area on wool fibre, the original magnifications from view A to view D are 500×, 1000×, 5000× and 10000×

respectively. Immobilization condition: Chlorinated woollen cloth, which was stored in 2% PEI solution at pH 8, was soaked in 2 mg ml^{-1} lipase solution pH 8.0 for 1 day, then cross-linked in 0.1% of GA solution prepared in 0.1 M phosphate buffer at pH 6.0 for 5 min. The images were taken after consecutive activity assay and all loss-associated lipases were washed off. Similarly to images above, view A is the general view of the cloth surface. In view B, one of badly etched wool fibre is highlighted, which is covered with some nodded structures. These structures are more closely viewed in the high magnification views of C and D.....126

Figure 6-7 ESEM image of non- lipase immobilized area on lipase immobilized woollen cloth prepared by the CRL protocol. The original magnifications from view A to view D are 500×, 2500 ×, 5000× and 20000× respectively. Immobilization condition: Chlorinated woollen cloth, which was stored in 2% PEI solution at pH 8, was soaked in 2 mg ml^{-1} lipase solution pH 8.0 for 1 day, then cross-linked in 0.1% of GA solution prepared in 0.1 M phosphate buffer at pH 6.0 for 5 min. The images were taken after consecutive activity assay and all loss-associated lipases were washed off. View A is the general view of the cloth surface. In view B, one of the fibre covered with a layer of sticky coating is highlighted. This film of coating is further detailed in the high magnification image of view C and view D. 127

CVB	immobilization via covalent binding method
CRL	immobilization via cross-linking method
DCCA	Dichlorocyanuric acid
DI water	Deioned water
GA	Glutaraldehyde
K_M	Parameter of Michaelis-Menten kinetic model
M-M kinetics	Michaelis-Menten kinetics
mTGase	Microbial Transglutaminase
PEI	polyethyleneimine
PFL	Lipase from *pseudomonas fluorescens*
pNPP	p-nitrophenol palmitate
pNP	p-nitrophenol
pNPA	p-nitrophenyl acetate
[S]	The concentration of the substrate
Tris buffer	Trizma buffer
UV spectra	ultraviolet and visible adsorption spectra
v	Reaction rate
v_{max}	Maximum reaction velocity in Michaelis-Menten kinetic model
