The Discriminative Functions of Primary and Conditional Reinforcers:
Signalling the Local and Global Contingencies of Reinforcement

Nathalie Boutros

A thesis submitted in partial fulfilment of the requirement for the degree of Doctor of

Philosophy

Abstract

In 4 experiments, pigeons worked in two-key concurrent schedules for food and non-food response-contingent events. Choice after one of these events was a function of the global and local relative probability of a same-alternative food. Experiment 1 was a steady-state two-alternative concurrent-schedule procedure with added response-contingent red keylights, whose left: right ratio was positively, negatively or zero-correlated with the left: right food ratio. Local preference after a red keylight was always towards the just-productive alternative, regardless of the stimulus ratio-food ratio correlation. Pairing the stimuli with food enhanced this effect. In Experiment 2, response-contingent keylights signalled the likely location ($p = .9$) of the next food, and preference was towards the locally richer alternative, whether this alternative was the just-reinforced or the not-just-reinforced alternative. When the two alternatives were equally likely to produce the next reinforcer, preference was towards the just-reinforced alternative. This was because the post-event changeover contingencies biased the local obtained food ratio. This was confirmed in Experiment 3 in which the post-food illuminated alternative was varied and food was the only response-contingent event. Local preference was always towards the post-food illuminated alternative when the reinforcers randomly alternated. When the reinforcers strictly alternated, preference was initially towards the post-food illuminated alternative before changing to the not-just-reinforced alternative. This finding confirmed that previous difficulties with strict-alternation were likely due to the post-food changeover contingencies biasing the perceived post-food obtained local reinforcer ratio. Experiment 3 also revealed that preference was shifted by same-alternative reinforcers (continuations) regardless of the post-food changeover contingencies, suggesting a response-strengthening function of temporally

distant reinforcers. Experiment 4 revealed that control by temporally distant reinforcers is apparently not discriminative: there was no control by the local probability of a same-alternative reinforcer ($p = 0$ or 1) when sequences of same-alternative reinforcers strictly alternated. Preference was instead a function of the global probability of a continuation reinforcer. Together, these experiments demonstrate that response-contingent stimuli (appetitive and non-appetitive) function as signals indicating the likely location of subsequent appetitive stimuli. They can signal the short-term, or the long-term contingencies of further appetitive stimuli, or both.

Acknowledgements

I would like to first thank my supervisors, Professor Michael Davison and Dr. Douglas Elliffe for the use of their equipment as well as for all of their expertise, advice, corrections, experience and support. Moreover, I thank them for allowing me the freedom to explore and to learn. This thesis never would have been completed without them. I also thank Mr. Mick Sibley for his excellent care of the subjects. I would also like to thank all of the students that have come through the operant lab in my time here. Thanks for helping to care for the animals, and thanks for some very interesting conversations. Lastly, I thank Neil Green for all of his support and care.
