109

110

111

## 112 **Standfirst:**

113 Open scholarship has transformed research, introducing a host of new terms in the  
114 lexicon of researchers. The Framework of Open and Reproducible Research Teaching (FORRT)  
115 community presents a crowdsourced glossary of open scholarship terms to facilitate education  
116 and effective communication between experts and newcomers.

117

## 118 **Barriers to Open Scholarship Terminology**

119 Open Scholarship is an umbrella term referring to the endeavour to improve openness,  
120 integrity, social justice, diversity, equity, inclusivity and accessibility in all areas of scholarly  
121 activities. Open Scholarship extends the more widely used terms "Open Science" and "Open  
122 Research" to include academic fields beyond the sciences and academic activities.

123 Over the last decade, Open Scholarship has radically changed the way we think and  
124 discuss research and higher education. New concepts, tools, and practices have been developed  
125 and promoted, introducing novel terms or repurposing existing ones. These changes have  
126 increased the breadth but also the ambiguity of terminology, creating barriers to effective  
127 understanding and communication for novices and experts. Presently, certain terms such as  
128 *replicability* or *reproducibility* are well known but frequently used interchangeably or  
129 differentially among fields and disciplines; other terms are less known beyond a small circle of  
130 researchers, such as *CARKing*, *PARKing*, or *paradata*. Terms that become conventional within a  
131 given field often reflect the preferences of those with the platforms and privileges to determine  
132 academic discourse and, consequently, can act as a barrier to participation by those without such  
133 platforms. A similar barrier is that much academic language is contained within a 'hidden  
134 curricula', meaning these terms and practices are often used under the misplaced assumption that  
135 students, or those unfamiliar with an area, understand them.

136

## 137 **A Diversity of New Terminologies**

138 Terms associated with Open Scholarship are diverse in many aspects. Some are  
139 neologisms (i.e., newly coined) while others are reclamations of older terms (e.g. *p-hacking* and  
140 adversarial collaboration). Furthermore, frequent use of acronyms can hinder immediate  
141 understanding. For example, ORCID iD<sup>1</sup> refers to a persistent unique identifier for individuals in  
142 their role as creator or contributor. It enables linking digital documents and other contributions to  
143 their digital records, attributes credit, and resolves name ambiguities. Other terms use metaphors,  
144 such as the *Garden of Forking Paths*<sup>2</sup>, which highlights the many alternative paths researchers  
145 can embark on when analysing data. These examples highlight the complexity of Open  
146 Scholarship terminology, which often assumes prior knowledge, making it difficult for  
147 individuals not versed in these terms to engage in ongoing conversations about these topics, thus  
148 excluding them from joining the discourse.

149

150 Communication across disciplines, and across dramatically varying levels of subject and  
151 technical expertise, can be extremely difficult. Challenges can arise in understanding scientific

152 texts when words with a historical meaning gain a new one in certain contexts. The term *paper*  
153 *mills*<sup>3</sup>, for example, typically refers to factories devoted to manufacturing papers but also, in the  
154 context of open scholarship, it denotes unethical for-profit organisations that create and publish  
155 on-demand fraudulent scientific papers based on techniques such as fabrication of data and  
156 plagiarism.

157 A similar challenge arises when the meaning and usage of certain terms differs between  
158 (sub)disciplines and methodologies. For example, in social science fields the term  
159 *preregistration* refers to an uneditable, timestamped version of a research protocol, whereas in  
160 healthcare fields it refers to an accelerated course that qualifies students to fast-track into a  
161 medical profession. As another example, social scientists understand the term *external validity* to  
162 mean that the findings can be generalised to other contexts (different measures, people, places,  
163 and times), while psychometricians regard it as the relationship of a psychological concept with  
164 theoretically relevant extrinsic variables. *Creative destruction*<sup>4</sup> is yet another example: in  
165 economics, it refers to revolutionising the economic structure from within by destroying the old  
166 system and replacing it with a new one. In psychology, a creative destruction approach to  
167 replication means that replications can—in particular circumstances—be leveraged to not only  
168 support or question the original findings, but also to replace weaker theories with stronger ones  
169 that have greater explanatory power (by preregistering different theoretical predictions and  
170 adding new measures, conditions and populations that facilitate competitive theory testing). As  
171 interdisciplinary collaboration is growing and often required by many funding agencies and  
172 stakeholders, this creates a potential for miscommunication and confusion when using such  
173 terminology.

174 The clarification of scholarly terminology is a challenging endeavour. It should be built  
175 on the insights of a community of experts with different perspectives and requires consensus  
176 among the members across disciplines. As the breadth of these initiatives can be overwhelming,  
177 digestible introductions to the language of Open Scholarship are needed<sup>5-7</sup>. In order to reduce  
178 barriers to entry and understanding of Open Scholarship terminology, as well as to foster the  
179 accessibility, inclusivity, and clarity of its language, a community-driven glossary using a  
180 consensus-based methodology could help clarify terminologies and aid in the mentoring and  
181 teaching of these concepts.

182

### 183 **The Open Scholarship Glossary Project**

184 The present glossary was developed by the FORRT<sup>7</sup> community; an educational initiative  
185 aiming to integrate open and reproducible research principles into higher education as well as  
186 supporting educators and mentors to address related pedagogical challenges. The work has been  
187 completed in three rounds. First, the lead team created an initial list of Open Scholarship related  
188 terms and a structure for each term. Each term was required to have (1) a concise *definition*; with  
189 supporting (2) *references*; (3) *related terms*; and (4) any applicable *alternative definitions*. The  
190 present glossary has been developed using a crowdsourced methodology with the involvement of  
191 over 100 contributors at various career stages and from a diverse range of disciplines, including

192 psychology, economics, neuroscience, information science, social science, biology, ecology,  
 193 public health, and linguistics. In the second round, and in a dynamic and iterative crowdsourced  
 194 process, members of the research community were invited through social media platforms or via  
 195 organisations such as *ReproducibiliTea* to participate in the project. The community contributors  
 196 suggested new terms, to which they provided main and alternative definitions, as well as  
 197 reviewed and edited other terms iteratively throughout the project. We recorded these  
 198 contributions, and this is reflected in our CRediT statement; all contributors were invited as  
 199 authors on this manuscript. We considered definitions as ready for dissemination when they had  
 200 been reviewed by a sufficient number of contributors (typically five or more) and reached  
 201 consensus. Through this process, the community-driven glossary development procedure  
 202 deliberately centred the Open Scholarship ethos of accessibility, diversity, equity, and inclusion.  
 203

204 The project resulted in the drafting of more than 250 terms. In Table 1, we present an  
 205 abbreviated set of 30 terms that represent the plurality of terms for the broader Open Scholarship  
 206 concepts (see <https://forrt.org/glossary> for the complete glossary, including key references and  
 207 links to related terms, as well as a more detailed explanation of the project's mission and goals).  
 208 The FORRT Glossary project is licensed under a CC BY NC SA 4.0 license. The present  
 209 glossary is the 1.0 version. The version-controlled source code of the new releases of the  
 210 complete Glossary is archived on FORRT's [website](#), [GitHub](#), [OSF](#), and [Zenodo](#), wherein new  
 211 releases will also be stored. We set up a system allowing for continuous improvement, extension,  
 212 and updating from community feedback and involvement. Versioning will also allow the study  
 213 of the evolution of the terminologies.  
 214

215 **Table 1 Open Scholarship Glossary 1.0 Examples (abbreviated version)**

216 *Note:* The complete glossary, including key references and links to related terms, can be found in  
 217 Supplementary Information and is available at <https://forrt.org/glossary>. Minor modifications  
 218 were made to comply with editorial requirements.

<b>Analytic Flexibility</b>	Analytic flexibility is a type of researcher degrees of freedom that refers specifically to the large number of choices made during data preprocessing and statistical analysis. Analytic flexibility can be problematic as this variability in analytic strategies can translate into variability in research outcomes, particularly when several strategies are applied, but not transparently reported.
<b>#bropenscience</b>	A tongue-in-cheek expression intended to raise awareness of the lack of diverse voices in open science, in addition to the presence of behavior and communication styles that can be toxic or exclusionary. Importantly, not all bros are men; rather, they are individuals who demonstrate rigid thinking, lack self-awareness, and tend towards hostility, unkindness, and exclusion. They generally belong to dominant groups who benefit from structural

	privileges. To address #bropenscience, researchers should examine and address structural inequalities within academic systems and institutions.
<b>CARKing</b>	Critiquing After the Results are Known (CARKing) refers to presenting a criticism of a design as one that you would have made in advance of the results being known. It usually forms a reaction or criticism to unwelcome or unfavourable results, whether the critic is conscious of this fact or not.
<b>Codebook</b>	A codebook is a high-level summary that describes the contents, structure, nature and layout of a data set. A well-documented codebook contains information intended to be complete and self-explanatory for each variable in a data file, such as the wording and coding of the item, and the underlying construct. It provides transparency to researchers who may be unfamiliar with the data but wish to reproduce analyses or reuse the data.
<b>Conceptual replication</b>	A replication attempt whereby the primary effect of interest is the same but tested in a different sample and captured in a different way to that originally reported (i.e., using different operationalisations, data processing and statistical approaches and/or different constructs). The purpose of a conceptual replication is often to explore what conditions limit the extent to which an effect can be observed and generalised (e.g., only within certain contexts, with certain samples, using certain measurement approaches) towards evaluating and advancing theory.
<b>Creative destruction approach</b>	Replication efforts should seek not just to support or question the original findings, but also to replace them with revised, stronger theories with greater explanatory power. This approach therefore involves ‘pruning’ existing theories, comparing all the alternative theories, and making replication efforts more generative and engaged in theory-building
<b>Credibility Revolution</b>	The problems and the solutions resulting from a growing distrust in scientific findings, following concerns about the credibility of scientific claims (e.g., low replicability). The term has been proposed as a more positive alternative to the term replicability crisis, and includes the many solutions to improve the credibility of research, such as preregistration, transparency, and replication.
<b>CRediT</b>	The Contributor Roles Taxonomy (CRediT; <a href="https://casrai.org/credit/">https://casrai.org/credit/</a> ) is a high-level taxonomy used to indicate the roles typically adopted by contributors to scientific scholarly output. There are currently 14 roles that describe each contributor’s specific contribution to the scholarly output.

	<p>They can be assigned multiple times to different authors and one author can also be assigned multiple roles. CRediT includes the following roles: Conceptualization, Data curation, Formal Analysis, Funding acquisition, Investigation, Methodology, Project administration, Resources, Software, Supervision, Validation, Visualization, Writing – original draft, Writing – review &amp; editing.</p>
<b>Decolonisation</b>	<p>Coloniality can be described as the naturalisation of concepts such as imperialism, capitalism, and nationalism. Together these concepts can be thought of as a matrix of power (and power relations) that can be traced to the colonial period. Decoloniality seeks to break down and decentralize those power relations, with the aim to understand their persistence and to reconstruct the norms and values of a given domain. In an academic setting, decolonisation refers to the rethinking of the lens through which we teach, research, and co-exist, so that the lens generalises beyond Western-centred and colonial perspectives. Decolonising academia involves reconstructing the historical and cultural frameworks being used, redistributing a sense of belonging in universities, and empowering and including voices and knowledge types that have historically been excluded from academia. This is done when people engage with their past, present, and future whilst holding a perspective that is separate from the socially dominant perspective. Also, by including, not rejecting, an individuals' internalised norms and taboos from the specific colony.</p>
<b>Direct replication</b>	<p>As 'direct replication' does not have a widely-agreed technical meaning nor there is no clear cut distinction between a direct and conceptual replication, below we list several contributions towards a consensus. Rather than debating the 'exactness' of a replication, it is more helpful to discuss the relevant differences between a replication and its target, and their implications for the reliability and generality of the target's results. Generally, direct replication refers to a new data collection that attempts to replicate original studies' methods as closely as possible. In this sense, direct replication is a replication attempt that aims to duplicate the needed elements that produced the original results.. The purpose of a direct replication can be to identify type 1 errors and/or experimenter effects, determine the replicability of an effect using the same or improved practices, or to create more specific estimates of effect size. Directness of replication is a continuum between repeating specific observations (data) and observing generalised effects (phenomena). How closely a replication replicates an original study is often a matter for debate, often with</p>

	<p>differences being cited as hidden moderators of effects. Furthermore, there can be debate over the relevant importance of technical equivalence (i.e., using identical materials) versus psychological equivalence (i.e., realizing the identical psychological conditions) to the original study. For example, consider a study on Trust in the US- President conducted in 2018. A technical equivalent replication would use Trump as stimulus (he was president in 2018) a psychological equivalent study would use Biden (he is the current president).</p>
<b>External Validity</b>	<p>Whether the findings of a scientific study can be generalized to other contexts outside the study context (different measures, settings, people, places, and times). Statistically, threats to external validity may reflect interactions whereby the effect of one factor (the independent variable) depends on another factor (a confounding variable). External validity may also be limited by the study design (e.g., an artificial laboratory setting or a non-representative sample). Alternative definition: In Psychometrics, the degree of evidence that confirms the relations of a tested psychological construct with external variables.</p>
<b>FAIR principles</b>	<p>Describes making scholarly materials Findable, Accessible, Interoperable and Reusable (FAIR). ‘Findable’ and ‘Accessible’ are concerned with where materials are stored (e.g. in data repositories), while ‘Interoperable’ and ‘Reusable’ focus on the importance of data formats and how such formats might change in the future.</p>
<b>Garden of forking paths</b>	<p>The typically-invisible decision tree traversed during operationalization and statistical analysis given that ‘there is a one-to-many mapping from scientific to statistical hypotheses’ (Gelman and Loken, 2013, p. 6). In other words, even in absence of p-hacking or fishing expeditions and when the research hypothesis was posited ahead of time, there can be a plethora of statistical results that can appear to be supported by theory given data. “The problem is there can be a large number of potential comparisons when the details of data analysis are highly contingent on data, without the researcher having to perform any conscious procedure of fishing or examining multiple p-values” (Gelman and Loken, 2013, p. 1). The term aims to highlight the uncertainty ensuing from idiosyncratic analytical and statistical choices in mapping theory-to-test, and contrasting intentional (and unethical) questionable research practices (e.g. p-hacking and fishing expeditions) versus non-intentional research practices that can, potentially, have the same effect despite not having intent to corrupt their results. The</p>

	garden of forking paths refers to the decisions during the scientific process that inflate the false-positive rate as a consequence of the potential paths which could have been taken (had other decisions been made).
<b>HARKING</b>	A questionable research practice termed ‘Hypothesizing After the Results are Known’ (HARKing). HARKing has been defined as a post hoc hypothesis which is either based on —or informed by— a result in a research report as if it was, in fact, a priori . For example, performing subgroup analyses, finding an effect in one subgroup, and writing the introduction with a ‘hypothesis’ that matches these results.
<b>Incentive Structure</b>	The set of evaluation and reward mechanisms (explicit and implicit) for scientists and their work. Incentivised areas within the broader structure include hiring and promotion practices, track record for awarding funding, and prestige indicators such as publication in journals with high impact factors, invited presentations, editorships, and awards. It is commonly believed that these criteria are often misaligned with the telos of science, and therefore do not promote rigorous scientific output. Initiatives like DORA aim to reduce the field’s dependency on evaluation criteria such as journal impact factors in favor of assessments based on the intrinsic quality of research outputs.
<b>Inclusion</b>	Inclusion, or inclusivity, refers to a sense of welcome and respect within a given collaborative project or environment (such as academia) where diversity simply indicates a wide range of backgrounds, perspectives, and experiences, efforts to increase inclusion go further to promote engagement and equal valuation among diverse individuals, who might otherwise be marginalized. Increasing inclusivity often involves minimising the impact of, or even removing, systemic barriers to accessibility and engagement.
<b>Metadata</b>	Structured data that describes and synthesises other data. Metadata can help find, organize, and understand data. Examples of metadata include creator, title, contributors, keywords, tags, as well as any kind of information necessary to verify and understand the results and conclusions of a study such as codebook on data labels, descriptions, the sample and data collection process. <i>Alternative definition</i> : data about data.
<b>Multi-analyst studies</b>	In typical empirical studies, a single researcher or research team conducts the analysis, which creates uncertainty about the extent to which the choice of analysis influences the results. In multi-analyst studies, two or more researchers independently analyse the same research question or hypothesis

	on the same dataset. A multi-analyst approach may be beneficial in increasing our confidence in a particular finding; uncovering the impact of analytical preferences across research teams; and highlighting the variability in such analytical approaches.
<b>Open Scholarship</b>	‘Open scholarship’ is often used synonymously with ‘open science’, but extends to all disciplines, drawing in those which might not traditionally identify as science-based. It reflects the idea that knowledge of all kinds should be openly shared, transparent, rigorous, reproducible, replicable, accumulative, and inclusive (allowing for all knowledge systems). Open scholarship includes all scholarly activities that are not solely limited to research such as teaching and pedagogy.
<b>Open Science</b>	An umbrella term reflecting the idea that scientific knowledge of all kinds, where appropriate, should be openly accessible, transparent, rigorous, reproducible, replicable, accumulative, and inclusive, all which are considered fundamental features of the scientific endeavour. Open science consists of principles and behaviors that promote transparent, credible, reproducible, and accessible science. Open science has six major aspects: open data, open methodology, open source, open access, open peer review, and open educational resources.
<b>ORCID iD</b>	An organisation that provides a registry of persistent unique identifiers (ORCID iDs) for researchers and scholars, allowing these users to link their digital research documents and other contributions to their ORCID record. This avoids the name ambiguity problem in scholarly communication. ORCID iDs provide unique, persistent identifiers connecting researchers and their scholarly work. It is free to register for an ORCID iD at <a href="https://orcid.org/register">https://orcid.org/register</a> .
<b>p-hacking</b>	Exploiting techniques that may artificially increase the likelihood of obtaining a statistically significant result by meeting the standard statistical significance criterion (typically $\alpha = .05$ ). For example, performing multiple analyses and reporting only those at $p < .05$ , selectively removing data until $p < .05$ , selecting variables for use in analyses based on whether those parameters are statistically significant.
<b>Papermill</b>	An organization that is engaged in scientific misconduct wherein multiple papers are produced by falsifying or fabricating data, e.g. by editing figures or numerical data or plagiarizing written text. A papermill relates to the fast

	production and dissemination of multiple allegedly new papers. These are often not detected in the scientific publishing process and therefore either never found or retracted if discovered (e.g. through plagiarism software).
<b>Paradata</b>	Data that are captured about the characteristics and context of primary data collected from an individual - distinct from metadata. Paradata can be used to investigate a respondent's interaction with a survey or an experiment on a micro-level. They can be most easily collected during computer mediated surveys but are not limited to them. Examples include response times to survey questions, repeated patterns of responses such as choosing the same answer for all questions, contextual characteristics of the participant such as injuries that prevent good performance on tasks, the number of premature responses to stimuli in an experiment. Paradata have been used for the investigation and adjustment of measurement and sampling errors.
<b>PARKing</b>	PARKing (preregistering after results are known) is defined as the practice where researchers complete an experiment (possibly with infinite re-experimentation) before preregistering. This practice invalidates the purpose of preregistration, and is one of the QRPs (or, even scientific misconduct) that try to gain only "credibility that it has been preregistered.
<b>Preregistration</b>	The practice of publishing the plan for a study, including research questions/hypotheses, research design, data analysis before the data has been collected or examined. It is also possible to preregister secondary data analyses. A preregistration document is time-stamped and typically registered with an independent party (e.g., a repository) so that it can be publicly shared with others (possibly after an embargo period). Preregistration provides a transparent documentation of what was planned at a certain time point, and allows third parties to assess what changes may have occurred afterwards. The more detailed a preregistration is, the better third parties can assess these changes and with that the validity of the performed analyses. Preregistration aims to clearly distinguish confirmatory from exploratory research.
<b>Replicability</b>	An umbrella term, used differently across fields, covering concepts of: direct and conceptual replication, computational reproducibility/replicability, generalizability analysis and robustness analyses. Some of the definitions used previously include: a different team arriving at the same results using the original author's artifacts; a study arriving at the same conclusion after collecting new data; as well as studies for which any outcome would be considered diagnostic evidence about a

	claim from prior research.
<b>Reproducibility</b>	A minimum standard on a spectrum of activities ("reproducibility spectrum") for assessing the value or accuracy of scientific claims based on the original methods, data, and code. For instance, where the original researcher's data and computer codes are used to regenerate the results, often referred to as computational reproducibility. Reproducibility does not guarantee the quality, correctness, or validity of the published results. In some fields, this meaning is, instead, associated with the term "replicability" or 'repeatability'.
<b>Registered Reports</b>	A scientific publishing format that includes an initial round of peer review of the background and methods (study design, measurement, and analysis plan); sufficiently high quality manuscripts are accepted for in-principle acceptance (IPA) at this stage. Typically, this stage 1 review occurs before data collection, however secondary data analyses are possible in this publishing format. Following data analyses and write up of results and discussion sections, the stage 2 review assesses whether authors sufficiently followed their study plan and reported deviations from it (and remains indifferent to the results). This shifts the focus of the review to the study's proposed research question and methodology and away from the perceived interest in the study's results.
<b>Under-representation</b>	Not all voices, perspectives, and members of the community are adequately represented. Under-representation typically occurs when the voices or perspectives of one group dominate, resulting in the marginalization of another. This often affects groups who are a minority in relation to certain personal characteristics.
<b>WEIRD</b>	This acronym refers to Western, Educated, Industrialized, Rich and Democratic societies. Most research is conducted on, and conducted by, relatively homogeneous samples from WEIRD societies. This limits the generalizability of a large number of research findings, particularly given that WEIRD people are often psychological outliers. It has been argued that "WEIRD psychology" started to evolve culturally as a result of societal changes and religious beliefs in the Middle Ages in Europe. Critics of this term suggest it presents a binary view of the global population and erases variation that exists both between and within societies, and that other aspects of diversity are not captured.

## 221 **Summary**

222 This glossary is a first step in creating a common language for these concepts, facilitating  
223 discussions about the strengths and weaknesses of different Open Scholarship practices, and  
224 ultimately helping to build a stronger research community<sup>8</sup>.

225 As with all terminologies, this glossary will be the subject of iterative improvement and  
226 updates. We encourage the scientific community to read the terms with critical eyes and to  
227 provide feedback and recommendations on FORRT's website, where instructions on how to  
228 contribute are provided and where the live version of all defined terms is publically available.

229

## 230 **Competing interests**

231 The other authors declare no competing interests.

232

## 233 **Data and materials availability**

234 All materials produced are available in its entirety at <https://forrt.org/glossary>

235

## 236 **Acknowledgements**

237 We would like to thank Dr. Eiko Fried and Professor Dr. Eric Uhlmann for helping steer  
238 the discussion and reviewing some Glossary terms.

239

## 240 **Author contributions**

241 **Conceptualization:** S.P., F.A., and B. Aczel.

242 **Data curation:** F.A. and S.G.

243 **Formal analysis:** F.A. and S.G.

244 **Investigation:** S.P. and F.A.

245 **Methodology:** S.P. and F.A.

246 **Project administration:** S.P. and F.A.

247 **Software:** F.A. and S.G.

248 **Validation:** S.P., F.A., M.M.E., and S.G.

249 **Visualization:** F.A. and S.G.

250 **Writing - original draft:** S.P., F.A., M.M.E., S.G., M.L.V., M.R.V., J.F.M., B. Arendt, J.T., M.
